Information-Theoretical Security for Several Models of Multiple-Access Channel

Bin Dai, A. J. Han Vinck, *Fellow, IEEE,* Zhuojun Zhuang, and Yuan Luo

Abstract

Several security models of multiple-access channel (MAC) are investigated. First, we study the degraded MAC with confidential messages, where two users transmit their confidential messages (no common message) to a destination, and each user obtains a degraded version of the output of the MAC. Each user views the other user as a eavesdropper, and wishes to keep its confidential message as secret as possible from the other user. Measuring each user's uncertainty about the other user's confidential message by equivocation, the inner and outer bounds on the capacity-equivocation region for this model have been provided. The result is further explained via the binary and Gaussian examples.

Second, the discrete memoryless multiple-access wiretap channel (MAC-WT) is studied, where two users transmit their corresponding confidential messages (no common message) to a legitimate receiver, while an additional wiretapper wishes to obtain the messages via a wiretap channel. This new model is considered into two cases: the general MAC-WT with cooperative encoders, and the degraded MAC-WT with non-cooperative encoders. The capacity-equivocation region is totally determined for the cooperative case, and inner and outer bounds on the capacity-equivocation region are provided for the non-cooperative case. For both cases, the results are further explained via the binary examples.

Index Terms

Confidential message, capacity-equivocation region, Gaussian MAC, multiple-access channel (MAC), secrecy capacity region, wiretap channel.

I. INTRODUCTION

Transmission of confidential messages has been studied in the literature of several classes of channels. Wyner, in his well-known paper on the wiretap channel [1], studied the problem that how to transmit the confidential messages to the legitimate receiver via a degraded broadcast channel, while keeping the wiretapper as ignorant of

the messages as possible. Measuring the uncertainty of the wiretapper by equivocation, the capacity-equivocation region was established. Furthermore, the secrecy capacity was also established, which provided the maximum transmission rate with perfect secrecy. After the publication of Wyner's work, Csiszár and Körner [2] investigated a more general situation: the broadcast channels with confidential messages (BCC). In this model, a common message and a confidential message were sent through a general broadcast channel. The common message was assumed to be decoded correctly by the legitimate receiver and the wiretapper, while the confidential message was only allowed to be obtained by the legitimate receiver. This model is also a generalization of [3], where no confidentiality condition is imposed. The capacity-equivocation region and the secrecy capacity region of BCC [2] were totally determined, and the results were also a generalization of those in [1]. Based on Wyner's work, Leung-Yan-Cheong and Hellman studied the Gaussian wiretap channel(GWC) [4], and showed that its secrecy capacity was the difference between the main channel capacity and the overall wiretap channel capacity (the cascade of main channel and wiretap channel). Some other related works on the wiretap channel (including feedback, side information and secret key) can be found in [5], [6], [7], [8], [9], [10].

Recently, the information-theoretical security for other multi-user communication systems has been investigated. The relay channel with confidential messages was studied in [11], and the interference channel with confidential messages was studied in [12]. For the multiple-access channel, the security problems are split into two directions. The first is that two users wish to transmit their corresponding messages to a destination, and meanwhile, they also receive the channel output. Each user treats the other user as a wiretapper, and wishes to keep its confidential message as secret as possible from the wiretapper. This model is usually called the MAC with confidential messages, and it was studied by [13], see Figure 1. An inner bound on the capacity-equivocation region is provided for the model of Figure 1, and the capacity-equivocation region is still not known. Furthermore, for the model of MAC with one confidential message [13], both inner and outer bounds on capacity-equivocation region are derived. Moreover, for the degraded MAC with one confidential message, the capacity-equivocation region is totally determined.

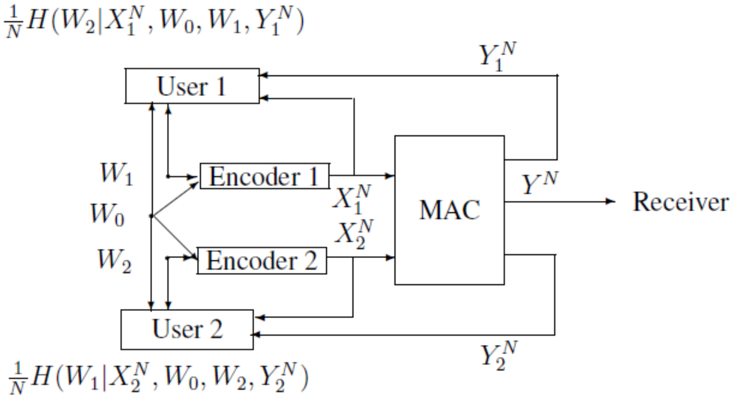

Fig. 1: MAC with confidential messages

The second is that an additional wiretapper has access to the MAC output via a wiretap channel, and therefore, how to keep the confidential messages of the two users as secret as possible from the additional wiretapper is the main concern of the system designer. This model is usually called the multiple-access wiretap channel (MAC-WT). The Gaussian MAC-WT was investigated by [14], see Figure 2. An inner bound on the capacity-equivocation region is provided for the Gaussian MAC-WT. Other related works on MAC-WT can be found in [15], [16].

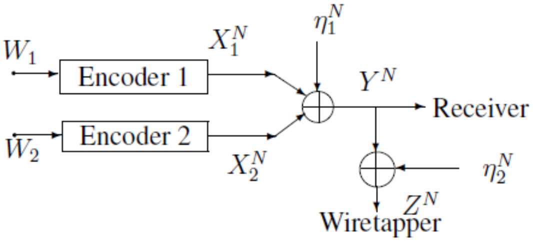

Fig. 2: Gaussian multiple-access wiretap channel

In this paper, firstly we study a special case of Figure 1, where two users wish to transmit their confidential messages (no common message) to a destination, and meanwhile, they also receive a degraded version of the channel output, see Figure 3. Each user wishes to keep its confidential message as secret as possible from the other user. Measuring each user's uncertainty about the other one's confidential message by equivocation, the inner and outer bounds on the capacity-equivocation region are provided for this model. Then, as examples, we establish the inner and outer bounds on the capacity-equivocation regions for the Gaussian and binary cases of Figure 3.

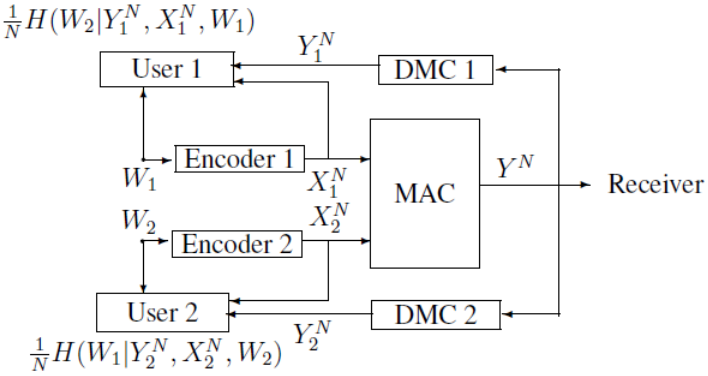

Fig. 3: Degraded MAC with confidential messages

Secondly we study the discrete memoryless multiple-access wiretap channel (MAC-WT), see Figure 4. The model of Figure 4 is considered into two cases: MAC-WT with cooperative encoders, and degraded MAC-WT with non-cooperative encoders. For the MAC-WT with cooperative encoders, the capacity-equivocation region is determined.

Furthermore, if the received symbols for the wiretapper is a degraded version of the symbols for the legitimate receiver (usually called degraded MAC-WT with cooperative encoders), we also establish the capacity-equivocation region for this special case. For the degraded MAC-WT with non-cooperative encoders, inner and outer bounds on the capacity-equivocation region are provided. Finally, as examples, we give the capacity-equivocation region for the binary degraded MAC-WT with cooperative encoders, and the secrecy capacity region for the binary degraded MAC-WT with non-cooperative encoders.

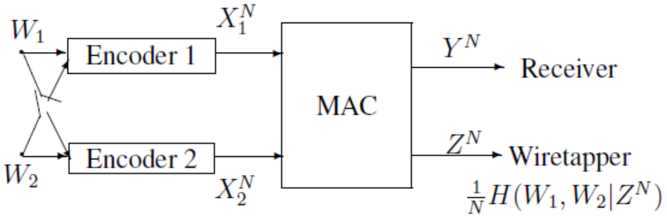

Fig. 4: Multiple-access wiretap channel with cooperative (or non-cooperative) encoders

In this paper, random variab1es, sample values and alphabets are denoted by capital letters, lower case letters and calligraphic letters, respectively. A similar convention is applied to the random vectors and their sample values. **For example, U^N denotes a random N-vector $(U_1, ..., U_N)$, and $u^N = (u_1, ..., u_N)$ is a specific vector value in $\mathcal{U}^N$ that is the Nth Cartesian power of $\mathcal{U}$. U_i^N denotes a random $N - i + 1$-vector $(U_i, ..., U_N)$, and $u_i^N = (u_i, ..., u_N)$ is a specific vector value in $\mathcal{U}_i^N$.** Let $p_V(v)$ denote the probability mass function $Pr\{V = v\}$. Throughout the paper, the logarithmic function is to the base 2.

The organization of this paper is as follows. In Section II, the capacity-equivocation region and the secrecy capacity region of the model of Figure 3 are determined in Theorem 1 and Remark 1, respectively. Then, as two examples, the capacity-equivocation region and the secrecy capacity region for the Gaussian and binary cases of Figure 3 are shown in Section III. In Section IV, the capacity-equivocation region and the secrecy capacity region for the model of Figure 4 with cooperative encoders are determined in Theorem 7 and Remark 3, respectively. The results of the degraded case for the model of Figure 4 with cooperative encoders are also shown in Section IV. The inner and outer bounds on the capacity-equivocation region for the model of Figure 4 with non-cooperative encoders are shown in Section V. In Section VI, we will show the binary examples about the model of Figure 4 with cooperative or non-cooperative encoders. Final conclusions are provided in Section VII.

II. DEGRADED MAC WITH CONFIDENTIAL MESSAGES

In this section, a description of the model of Figure 3 is given by Definition 1 to Definition 3. The capacity-equivocation region $\mathcal{R}^{(\mathcal{A})}$ composed of all achievable $(R_1, R_2, R_{e1}, R_{e2})$ tuples in the model of Figure 3 is characterized in Theorem 1, where the achievable $(R_1, R_2, R_{e1}, R_{e2})$ tuple is defined in Definition 4.

Definition 1: (**Encoders**) The confidential messages W_1 and W_2 take values in $\mathcal{W}_1$ and $\mathcal{W}_2$, respectively. W_1 and W_2 are independent and uniformly distributed over their ranges. Since each encoder is a wiretapper for the other encoder, the cooperation between the encoders is not allowed. The input and output of encoder 1 are W_1 and X_1^N, respectively. Similarly, the input and output of encoder 2 are W_2 and X_2^N, respectively. We assume that the encoders are stochastic encoders, i.e., the encoder f_i^N $(i = 1, 2)$ is a matrix of conditional probabilities $f_i^N(x_i^N|w_i)$, where $x_i^N \in \mathcal{X}_i^N$, $w_i \in \mathcal{W}_i$, and $f_i^N(x_i^N|w_i)$ is the probability that the message w_i is encoded as the channel input x_i^N. Note that W_1 and X_2^N are independent, and W_2 is independent of X_1^N.

The transmission rates of the confidential messages are $\frac{\log\|\mathcal{W}_1\|}{N}$ and $\frac{\log\|\mathcal{W}_2\|}{N}$.

Definition 2: (**Channels**) The MAC is a DMC with finite input alphabet $\mathcal{X}_1 \times \mathcal{X}_2$, finite output alphabet $\mathcal{Y}$, and transition probability $Q_1(y|x_1, x_2)$, where $x_1 \in \mathcal{X}_1, x_2 \in \mathcal{X}_2, y \in \mathcal{Y}$. $Q_1(y^N|x_1^N, x_2^N) = \prod_{n=1}^N Q_1(y_n|x_{1,n}, x_{2,n})$. The inputs of the MAC are X_1^N and X_2^N, while the output is Y^N.

User i $(i = 1, 2)$ has access to the output of the MAC via channel i. Channel i is a DMC with input Y^N and output Y_i^N. User 2's equivocation about W_1 is defined as

$$\Delta_1 = \frac{1}{N}H(W_1|Y_2^N, W_2, X_2^N) \overset{(a)}{=} \frac{1}{N}H(W_1|Y_2^N, X_2^N), \tag{2.1}$$

and user 1's equivocation about W_2 is defined as

$$\Delta_2 = \frac{1}{N}H(W_2|Y_1^N, W_1, X_1^N) \overset{(b)}{=} \frac{1}{N}H(W_2|Y_1^N, X_1^N), \tag{2.2}$$

where (a) and (b) are from $W_2 \rightarrow (Y_2^N, X_2^N) \rightarrow W_1$ and $W_1 \rightarrow (Y_1^N, X_1^N) \rightarrow W_2$.

Definition 3: (**Decoder**) The decoder is a mapping $f_D : \mathcal{Y}^N \rightarrow \mathcal{W}_1 \times \mathcal{W}_2$, with input Y^N and outputs $\widehat{W_1}$, $\widehat{W_2}$. Let P_e be the error probability of the receiver , and it is defined as $Pr\{(W_1, W_2) \neq (\widehat{W_1}, \widehat{W_2})\}$.

Definition 4: (**Achievable $(R_1, R_2, R_{e1}, R_{e2})$ tuple in the model of Figure 3**) A tuple $(R_1, R_2, R_{e1}, R_{e2})$ (where $R_1, R_2, R_{e1}, R_{e2} > 0$) is called achievable if, for any $\epsilon > 0$ (where ϵ is an arbitrary small positive real number and $\epsilon \rightarrow 0$), there exists a channel encoder-decoder $(N, \Delta_1, \Delta_2, P_e)$ such that

$$\lim_{N\rightarrow\infty} \frac{\log \parallel \mathcal{W}_1 \parallel}{N} = R_1, \lim_{N\rightarrow\infty} \frac{\log \parallel \mathcal{W}_2 \parallel}{N} = R_2, \lim_{N\rightarrow\infty} \Delta_1 \geq R_{e1}, \lim_{N\rightarrow\infty} \Delta_2 \geq R_{e2}, P_e \leq \epsilon. \tag{2.3}$$

The capacity-equivocation region $\mathcal{R}^{(A)}$ is a set composed of all achievable $(R_1, R_2, R_{e1}, R_{e2})$ tuples. The inner and outer bounds on the capacity-equivocation region $\mathcal{R}^{(A)}$ are provided in Theorem 1 and Theorem 2, respectively, and they are proved in Appendix A and Appendix B.

Theorem 1: **(Inner bound)** A single-letter characterization of the region $\mathcal{R}^{(Ai)}$ is as follows,

$$\begin{aligned}
&\mathcal{R}^{(Ai)} = \{(R_1, R_2, R_{e1}, R_{e2}) : 0 \leq R_{e1} \leq R_1, 0 \leq R_{e2} \leq R_2,\\
&0 \leq R_1 \leq I(X_1; Y|X_2),\\
&0 \leq R_2 \leq I(X_2; Y|X_1),\\
&R_1 + R_2 \leq I(X_1, X_2; Y),\\
&R_{e1} \leq I(X_1; Y|X_2) - I(X_1; Y_2|X_2),
\end{aligned}$$

$$R_{e2} \leq I(X_2;Y|X_1) - I(X_2;Y_1|X_1),$$

$$R_{e1} + R_{e2} \leq I(X_1,X_2;Y) - I(X_1;Y_2|X_2) - I(X_2;Y_1|X_1),$$

$$R_{e1} + R_2 \leq I(X_1,X_2;Y) - I(X_1;Y_2|X_2),$$

$$R_{e2} + R_1 \leq I(X_1,X_2;Y) - I(X_2;Y_1|X_1)\},$$

where $(X_1,X_2) \rightarrow Y \rightarrow (Y_1,Y_2)$ and $\mathcal{R}^{(Ai)} \subseteq \mathcal{R}^{(A)}$.

Remark 1: There are some notes on Theorem 1, see the following.

- The region $\mathcal{R}^{(\mathcal{A})}$ is convex, and the proof is directly obtained by introducing a time sharing random variable into Theorem 1, and therefore, we omit the proof here.
- Note that Theorem 1 indicates a tradeoff between the two equivocations R_{e1} and R_{e2}, i.e., $R_{e1} + R_{e2} \leq I(X_1,X_2;Y) - I(X_1;Y_2|X_2) - I(X_2;Y_1|X_1)$.
- The achievable secrecy region $\mathcal{C}_s^{(Ai)}$ is the set of pairs (R_1,R_2) such that $(R_1,R_2,R_{e1}=R_1,R_{e2}=R_2) \in \mathcal{R}^{(Ai)}$.

Corollary 1:

$$\mathcal{C}_s^{(Ai)} = \{(R_1,R_2) : R_1 \leq I(X_1;Y|X_2) - I(X_1;Y_2|X_2),$$

$$R_2 \leq I(X_2;Y|X_1) - I(X_2;Y_1|X_1),$$

$$R_1 + R_2 \leq I(X_1,X_2;Y) - I(X_1;Y_2|X_2) - I(X_2;Y_1|X_1)\}.$$

Proof: Corollary 1 is easy to be checked by substituting $R_{e1} = R_1$ and $R_{e2} = R_2$ into $\mathcal{R}^{(Ai)}$. ■

Theorem 2: **(Outer bound)** A single-letter characterization of the region $\mathcal{R}^{(Ao)}$ is as follows,

$$\mathcal{R}^{(Ao)} = \{(R_1,R_2,R_{e1},R_{e2}) : 0 \leq R_{e1} \leq R_1, 0 \leq R_{e2} \leq R_2,$$

$$0 \leq R_1 \leq I(X_1;Y|X_2),$$

$$0 \leq R_2 \leq I(X_2;Y|X_1),$$

$$R_1 + R_2 \leq I(X_1,X_2;Y),$$

$$R_{e1} \leq I(X_1;Y|X_2) - I(X_1;Y_2|X_2),$$

$$R_{e2} \leq I(X_2;Y|X_1) - I(X_2;Y_1|X_1)\},$$

where $(X_1,X_2) \rightarrow Y \rightarrow (Y_1,Y_2)$ and $\mathcal{R}^{(A)} \subseteq \mathcal{R}^{(Ao)}$.

Remark 2: There are some notes on Theorem 2, see the following.

- The region $\mathcal{R}^{(\mathcal{A})}$ is convex, and the proof is omitted here.
- The outer bound $\mathcal{C}_s^{(Ao)}$ on the secrecy capacity region is the set of pairs (R_1,R_2) such that $(R_1,R_2,R_{e1} = R_1,R_{e2} = R_2) \in \mathcal{R}^{(Ao)}$.

Corollary 2:

$$\mathcal{C}_s^{(Ao)} = \{(R_1, R_2) : R_1 \leq I(X_1; Y|X_2) - I(X_1; Y_2|X_2),$$
$$R_2 \leq I(X_2; Y|X_1) - I(X_2; Y_1|X_1),$$
$$R_1 + R_2 \leq I(X_1, X_2; Y)\}.$$

Proof: Corollary 2 is easy to be checked by substituting $R_{e1} = R_1$ and $R_{e2} = R_2$ into $\mathcal{R}^{(Ao)}$. ■

III. GAUSSIAN AND BINARY MACS WITH CONFIDENTIAL MESSAGES

A. The Gaussian Case of the Model of Figure 3

In this subsection, we study the Gaussian case of Figure 3, where the channel input-output relationships at each time instant i $(1 \leq i \leq N)$ are given by

$$Y_i = X_{1,i} + X_{2,i} + Z_i, \tag{3.4}$$

$$Y_{1,i} = X_{1,i} + X_{2,i} + Z_i + Z_{1,i}, \tag{3.5}$$

and

$$Y_{2,i} = X_{1,i} + X_{2,i} + Z_i + Z_{2,i}, \tag{3.6}$$

where $Z_i \sim \mathcal{N}(0, N_0)$, $Z_{1,i} \sim \mathcal{N}(0, N_1)$ and $Z_{2,i} \sim \mathcal{N}(0, N_2)$. The random vectors Z^N, Z_1^N and Z_2^N are independent with i.i.d. components. The channel inputs X_1^N and X_2^N are subject to the average power constraints P_1 and P_2, respectively, i.e.,

$$\frac{1}{N}\sum_{i=1}^{N} E[X_{1,i}^2] \leq P_1, \qquad \frac{1}{N}\sum_{i=1}^{N} E[X_{2,i}^2] \leq P_2. \tag{3.7}$$

The following Theorem 3 and Theorem 4 provide inner and outer bounds on the capacity-equivocation region of Gaussian MAC with confidential messages.

Theorem 3: For the Gaussian case of Figure 3, the inner bound $\mathcal{R}^{(Bi)}$ on the capacity-equivocation region $\mathcal{R}^{(\mathcal{B})}$

is given by

$$\mathcal{R}^{(Bi)} = \bigcup_{0\leq\alpha\leq 1, 0\leq\beta\leq 1} \left\{ \begin{array}{l} (R_1, R_2, R_{e1}, R_{e2}) : \\ 0 \leq R_1 \leq \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0}) \\ 0 \leq R_2 \leq \frac{1}{2}\log(1+\frac{\beta P_2}{N_0}) \\ R_1 + R_2 \leq \frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\alpha)P_1P_2}}{N_0}) \\ R_1 + R_2 \leq \frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\beta)P_1P_2}}{N_0}) \\ 0 \leq R_{e1} \leq R_1 \\ 0 \leq R_{e2} \leq R_2 \\ R_{e1} \leq \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0}) - \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2}) \\ R_{e2} \leq \frac{1}{2}\log(1+\frac{\beta P_2}{N_0}) - \frac{1}{2}\log(1+\frac{\beta P_2}{N_0+N_1}) \\ R_{e1} + R_{e2} \leq \frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\alpha)P_1P_2}}{N_0}) - \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2}) - \frac{1}{2}\log(1+\frac{\beta P_2}{N_0+N_1}) \\ R_{e1} + R_{e2} \leq \frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\beta)P_1P_2}}{N_0}) - \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2}) - \frac{1}{2}\log(1+\frac{\beta P_2}{N_0+N_1}) \\ R_{e1} + R_2 \leq \frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\alpha)P_1P_2}}{N_0}) - \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2}) \\ R_{e2} + R_1 \leq \frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\beta)P_1P_2}}{N_0}) - \frac{1}{2}\log(1+\frac{\beta P_2}{N_0+N_1}). \end{array} \right\}. \tag{3.8}$$

Proof: See Appendix C. ■

Corollary 3: The inner bound on the secrecy capacity region of the Gaussian case of Figure 3 is

$$\mathcal{C}_s^{(Bi)} = \bigcup_{0\leq\alpha\leq 1, 0\leq\beta\leq 1} \left\{ \begin{array}{l} (R_1, R_2) : \\ R_1 + R_2 \leq \frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\alpha)P_1P_2}}{N_0}) - \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2}) - \frac{1}{2}\log(1+\frac{\beta P_2}{N_0+N_1}) \\ R_1 + R_2 \leq \frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\beta)P_1P_2}}{N_0}) - \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2}) - \frac{1}{2}\log(1+\frac{\beta P_2}{N_0+N_1}) \\ R_1 \leq \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0}) - \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2}) \\ R_2 \leq \frac{1}{2}\log(1+\frac{\beta P_2}{N_0}) - \frac{1}{2}\log(1+\frac{\beta P_2}{N_0+N_1}). \end{array} \right\}. \tag{3.9}$$

Proof: Substituting $R_{e1} = R_1$ and $R_{e2} = R_2$ into the region $\mathcal{R}^{(Bi)}$ in Theorem 3, Corollary 3 is easily obtained. ■

The inner bound on the secrecy capacity $C_s^{(Bi)}(R_2)$ as a function of R_2 is

$$C_s^{(Bi)}(R_2) = \max_{\alpha} \min \left\{ \begin{array}{l} \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0}) - \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2}), \\ \frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\alpha)P_1P_2}}{N_0}) - \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2}) - \frac{1}{2}\log(1+\frac{\beta^* P_2}{N_0+N_1}) - R_2, \\ \frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\beta^*)P_1P_2}}{N_0}) - \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2}) - \frac{1}{2}\log(1+\frac{\beta^* P_2}{N_0+N_1}) - R_2, \end{array} \right\} \tag{3.10}$$

where β^* is determined by the following equation:

$$\frac{1}{2}\log(1+\frac{\beta^* P_2}{N_0}) - \frac{1}{2}\log(1+\frac{\beta^* P_2}{N_0+N_1}) = R_2. \tag{3.11}$$

Proof: The proof of (3.10) follows directly from Corollary 3. ■

Theorem 4: For the Gaussian case of Figure 3, the outer bound $\mathcal{R}^{(Bo)}$ on the capacity-equivocation region $\mathcal{R}^{(\mathcal{B})}$

is given by

$$\mathcal{R}^{(Bo)}=\bigcup_{0\leq\alpha\leq1,0\leq\beta\leq1}\left\{\begin{array}{l}(R_1,R_2,R_{e1},R_{e2}):\\ 0\leq R_1\leq\frac{1}{2}\log(1+\frac{\alpha P_1}{N_0})\\ 0\leq R_2\leq\frac{1}{2}\log(1+\frac{\beta P_2}{N_0})\\ R_1+R_2\leq\frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\alpha)P_1P_2}}{N_0})\\ R_1+R_2\leq\frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\beta)P_1P_2}}{N_0})\\ R_{e1}\leq R_1\\ R_{e2}\leq R_2\\ R_{e1}\leq\frac{1}{2}\log(1+\frac{\alpha P_1}{N_0})-\frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2})\\ R_{e2}\leq\frac{1}{2}\log(1+\frac{\beta P_2}{N_0})-\frac{1}{2}\log(1+\frac{\beta P_2}{N_0+N_1}).\end{array}\right\}. \tag{3.12}$$

Proof: See Appendix C. ■

Corollary 4: The outer bound on the secrecy capacity region of the Gaussian case of Figure 3 is

$$\mathcal{C}_s^{(Bo)}=\bigcup_{0\leq\alpha\leq1,0\leq\beta\leq1}\left\{\begin{array}{l}(R_1,R_2):\\ R_1+R_2\leq\frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\alpha)P_1P_2}}{N_0})\\ R_1+R_2\leq\frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\beta)P_1P_2}}{N_0})\\ R_1\leq\frac{1}{2}\log(1+\frac{\alpha P_1}{N_0})-\frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2})\\ R_2\leq\frac{1}{2}\log(1+\frac{\beta P_2}{N_0})-\frac{1}{2}\log(1+\frac{\beta P_2}{N_0+N_1}).\end{array}\right\}. \tag{3.13}$$

Proof: Substituting $R_{e1}=R_1$ and $R_{e2}=R_2$ into the region $\mathcal{R}^{(Bo)}$ in Theorem 4, Corollary 4 is easily obtained. ■

The outer bound on the secrecy capacity $C_s^{(Bo)}(R_2)$ as a function of R_2 is

$$C_s^{(Bo)}(R_2)=\max_{\alpha}\min\left\{\begin{array}{l}\frac{1}{2}\log(1+\frac{\alpha P_1}{N_0})-\frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2}),\\ \frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\alpha)P_1P_2}}{N_0})-R_2,\\ \frac{1}{2}\log(1+\frac{P_1+P_2+2\sqrt{(1-\beta^*)P_1P_2}}{N_0})-R_2,\end{array}\right\} \tag{3.14}$$

where β^* is determined by the following equation:

$$\frac{1}{2}\log(1+\frac{\beta^*P_2}{N_0})-\frac{1}{2}\log(1+\frac{\beta^*P_2}{N_0+N_1})=R_2. \tag{3.15}$$

Proof: The proof of (3.14) follows directly from Corollary 4. ■

Figure 5 plots the inner and outer bounds on the secrecy capacity of the Gaussian case of Figure 3 for three values of N_1 and N_2. The lines of $C_s^{(Bi)}(R_2)$ and $C_s^{(Bo)}(R_2)$ also serve as the boundaries of the inner and outer bounds on the secrecy capacity regions if we view the vertical axis as R_1. It is easy to see that as N_1 and N_2 increase, which implies that the noise level of the wiretap channels to both users increases, both users become more confused by the channel outputs. Thus, the inner and outer bounds on the secrecy capacity region enlarge.

B. The Binary Case of the Model of Figure 3

In this subsection, we study the following binary case of Figure 3. Assume that all channel inputs and outputs take values in $\{0,1\}$, and the channels are discrete memoryless. The input-output relationship of the channels at

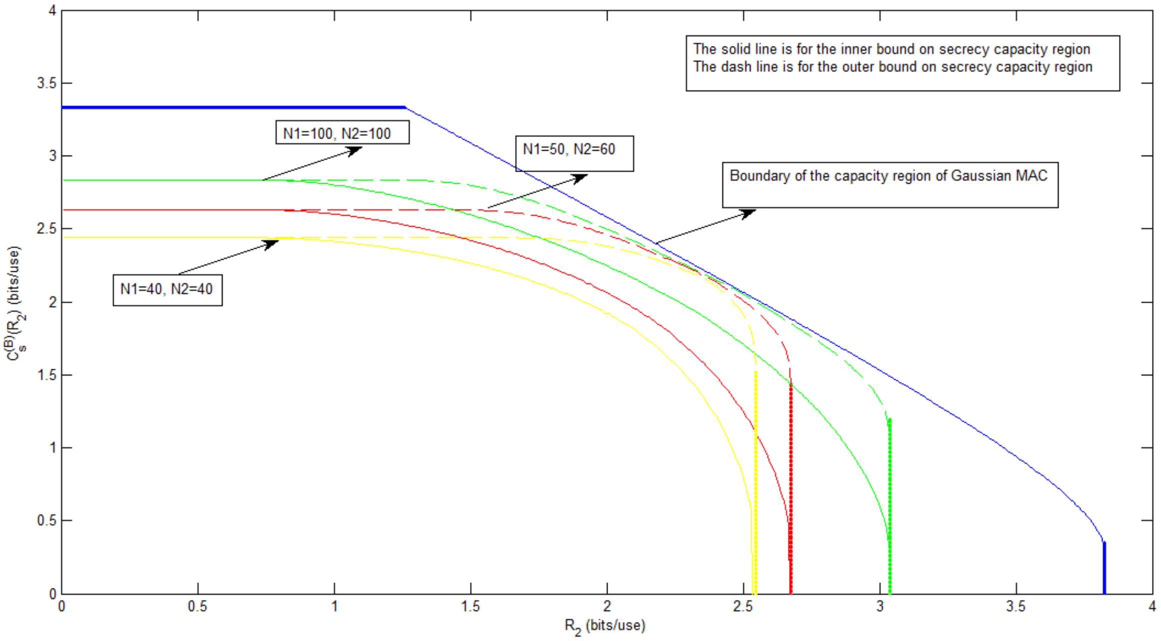

Fig. 5: Inner and outer bounds on the secrecy capacity regions of the Gaussian case of Figure 3 and capacity region of corresponding Gaussian MAC

each time instant satisfies

$$Y_i = X_{1,i} \cdot X_{2,i}, Y_{1,i} = Y_i \oplus Z_{1,i}, Y_{2,i} = Y_i \oplus Z_{2,i}, \tag{3.16}$$

where $1 \leq i \leq N$, and Z_1^N, Z_2^N are composed of N i.i.d. random variables with distributions $Pr\{Z_{1,i} = 1\} = p$ and $Pr\{Z_{2,i} = 1\} = q$, respectively. Let $0 \leq p, q \leq \frac{1}{2}$.

The following Theorem 6 and Theorem 5 provide inner and outer bounds on the capacity-equivocation region of the binary MAC with confidential messages.

Theorem 5: For the binary case of Figure 3, the inner bound on the capacity-equivocation region $\mathcal{R}^{(\mathcal{C})}$ is given by

$$\mathcal{R}^{(Ci)} = \bigcup_{0\leq\alpha\leq1, 0\leq\beta\leq1} \left\{ (R_1, R_2, R_{e1}, R_{e2}) : \begin{array}{l} 0 \leq R_1 \leq 1 \\ 0 \leq R_2 \leq 1 \\ R_1 + R_2 \leq 1 \\ 0 \leq R_{e1} \leq R_1, 0 \leq R_{e2} \leq R_2 \\ R_{e1} \leq h(q) \\ R_{e2} \leq h(p) \\ R_{e1} + R_{e2} \leq h(p) + h(q) - 1 \\ R_{e1} + R_2 \leq h(q) \\ R_{e2} + R_1 \leq h(p) \end{array} \right\}, \tag{3.17}$$

where $h(p) = -p\log(p) - (1-p)\log(1-p)$, and $h(q) = -q\log(q) - (1-q)\log(1-q)$.

Proof: See Appendix D. ■

Corollary 5: The inner bound on the secrecy capacity region of the binary case of Figure 3 is

$$\mathcal{C}_s^{(Ci)} = \bigcup_{0\leq\alpha\leq1, 0\leq\beta\leq1} \left\{ (R_1, R_2) : \begin{array}{l} R_1 + R_2 \leq h(p) + h(q) - 1 \\ R_1 \leq h(q) \\ R_2 \leq h(p) \end{array} \right\}. \tag{3.18}$$

Proof: Substituting $R_{e1} = R_1$ and $R_{e2} = R_2$ into the region $\mathcal{R}^{(Ci)}$ in Theorem 5, Corollary 5 is easily obtained. ■

Theorem 6: For the binary case of Figure 3, the outer bound on the capacity-equivocation region $\mathcal{R}^{(\mathcal{C})}$ is given by

$$\mathcal{R}^{(Co)} = \bigcup_{0\leq\alpha\leq1, 0\leq\beta\leq1} \left\{ (R_1, R_2, R_{e1}, R_{e2}) : \begin{array}{l} 0 \leq R_1 \leq 1 \\ 0 \leq R_2 \leq 1 \\ R_1 + R_2 \leq 1 \\ 0 \leq R_{e1} \leq R_1, 0 \leq R_{e2} \leq R_2 \\ R_{e1} \leq h(q) \\ R_{e2} \leq h(p) \end{array} \right\}, \tag{3.19}$$

where $h(p) = -p\log(p) - (1-p)\log(1-p)$, and $h(q) = -q\log(q) - (1-q)\log(1-q)$.

Proof: See Appendix D. ■

Corollary 6: The outer bound on the secrecy capacity region of the binary case of Figure 3 is

$$\mathcal{C}_s^{(Co)} = \bigcup_{0\leq\alpha\leq1, 0\leq\beta\leq1} \left\{ (R_1, R_2) : \begin{array}{l} R_1 + R_2 \leq 1 \\ R_1 \leq h(q) \\ R_2 \leq h(p) \end{array} \right\}. \tag{3.20}$$

Proof: Substituting $R_{e1} = R_1$ and $R_{e2} = R_2$ into the region $\mathcal{R}^{(Co)}$ in Theorem 5, Corollary 6 is easily obtained. ■

Figure 6 plots the inner and outer bounds on the secrecy capacity of the binary case of Figure 3 for $h(q) = 0.6$ and $h(p) = 0.8$. Note that p and q are the cross-over probabilities of the wiretap channels to both users, and as p

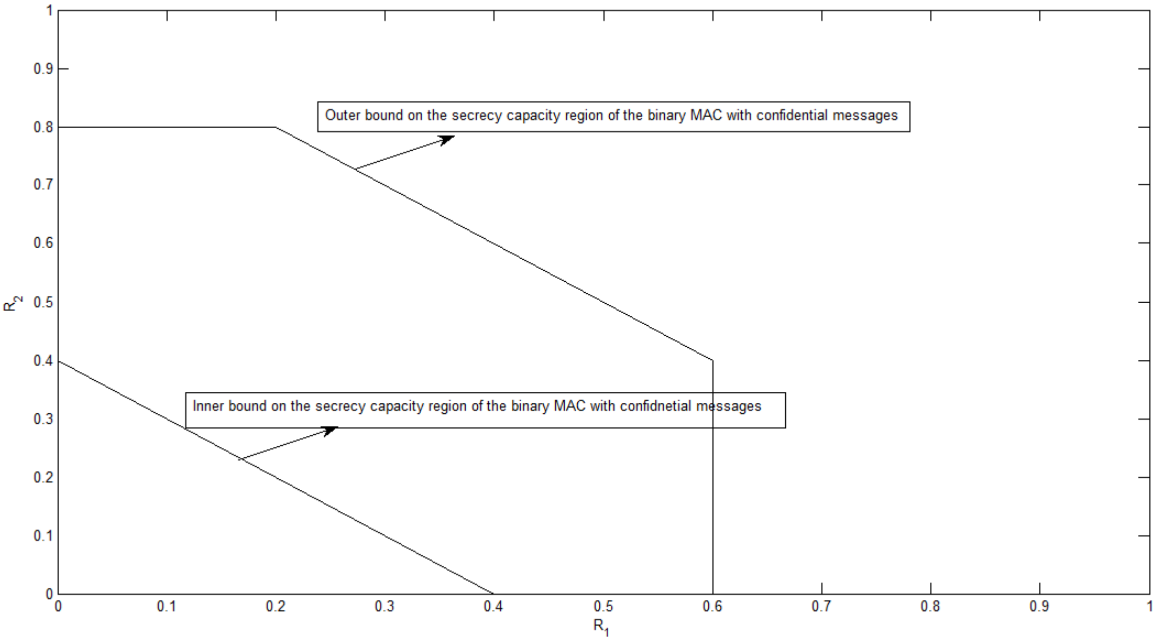

Fig. 6: Inner and outer bounds on the secrecy capacity region of the binary case of Figure 3

and q increase, both users become more and more confused by the channel outputs. When $p = q = \frac{1}{2}$, the inner and outer bounds on the secrecy capacity region are the same as the capacity region of the MAC.

IV. MULTIPLE ACCESS WIRETAP CHANNEL WITH COOPERATIVE ENCODERS

In this section, a description of the model of Figure 4 is given by Definition 5 to Definition 7. The capacity-equivocation region $\mathcal{R}^{(\mathcal{D})}$ composed of all achievable (R_1, R_2, R_e) triples in the model of Figure 4 is characterized in Theorem 7, where the achievable (R_1, R_2, R_e) triple is defined in Definition 8. The capacity-equivocation region of the degraded MAC-WT with cooperative encoders is given in Theorem 8.

Definition 5: (**Cooperative encoders**) The confidential messages W_1 and W_2 take values in $\mathcal{W}_1$ and $\mathcal{W}_2$, respectively. W_1 and W_2 are independent and uniformly distributed over their ranges. The inputs of the two encoders are W_1 and W_2, while the output of encoder 1 is X_1^N and the output of encoder 2 is X_2^N. We assume that the encoders are stochastic encoders, i.e., the encoder g_i^N $(i = 1, 2)$ is a matrix of conditional probabilities $g_i^N(x_i^N|w_1, w_2)$, where $x_i^N \in \mathcal{X}_i^N$, $w_i \in \mathcal{W}_i$, and $g_i^N(x_i^N|w_1, w_2)$ is the probability that the messages w_1 and w_2 are encoded as the channel input x_i^N. **Note that X_1^N and X_2^N are not independent.**

The transmission rates of the confidential messages are $\frac{\log\|\mathcal{W}_1\|}{N}$ and $\frac{\log\|\mathcal{W}_2\|}{N}$.

Definition 6: (**Channel**) The MAC-WT is a DMC with finite input alphabet $\mathcal{X}_1 \times \mathcal{X}_2$, finite output alphabet $\mathcal{Y} \times \mathcal{Z}$, and transition probability $Q_1(y, z|x_1, x_2)$, where $x_1 \in \mathcal{X}_1, x_2 \in \mathcal{X}_2, y \in \mathcal{Y}, z \in \mathcal{Z}$. $Q_1(y^N, z^N|x_1^N, x_2^N) = \prod_{n=1}^{N} Q_1(y_n, z_n|x_{1,n}, x_{2,n})$. The inputs of the channel are X_1^N and X_2^N, while the outputs are Y^N and Z^N.

The wiretapper's equivocation to the confidential messages W_1 and W_2 is defined as

$$\Delta = \frac{1}{N} H(W_1, W_2 | Z^N). \tag{4.1}$$

Definition 7: (**Decoder**) The decoder is a mapping $f_D : \mathcal{Y}^N \to \mathcal{W}_1 \times \mathcal{W}_2$, with input Y^N and outputs $\widehat{W}_1$, $\widehat{W}_2$. Let P_e be the error probability of the receiver , and it is defined as $Pr\{(W_1, W_2) \neq (\widehat{W}_1, \widehat{W}_2)\}$.

Definition 8: (**Achievable** (R_1, R_2, R_e) **triple in the model of Figure 4**) A triple (R_1, R_2, R_e) (where $R_1, R_2, R_e > 0$) is called achievable if, for any $\epsilon > 0$ (where ϵ is an arbitrary small positive real number and $\epsilon \to 0$), there exists a channel encoder-decoder (N, Δ, P_e) such that

$$\lim_{N \to \infty} \frac{\log \parallel \mathcal{W}_1 \parallel}{N} = R_1, \lim_{N \to \infty} \frac{\log \parallel \mathcal{W}_2 \parallel}{N} = R_2, \lim_{N \to \infty} \Delta \geq R_e, P_e \leq \epsilon. \tag{4.2}$$

Theorem 7 gives a single-letter characterization of the set $\mathcal{R}^{(\mathcal{D})}$, which is composed of all achievable (R_1, R_2, R_e) triples in the model of Figure 4, and it is proved in Appendix E and Appendix F.

Theorem 7: A single-letter characterization of the region $\mathcal{R}^{(\mathcal{D})}$ is as follows,

$$\begin{aligned}
&\mathcal{R}^{(\mathcal{D})} = \{(R_1, R_2, R_e) : R_e \leq R_1 + R_2, \\
&0 \leq R_1 \leq I(V; Y | U_2), \\
&0 \leq R_2 \leq I(V; Y | U_1), \\
&R_1 + R_2 \leq I(V; Y), \\
&R_e \leq I(V; Y | U) - I(V; Z | U)\},
\end{aligned}$$

where $(U, U_1, U_2) \to V \to (X_1, X_2) \to (Y, Z)$, and U, U_1, U_2 may be assumed to be (deterministic) functions of V.

Remark 3: There are some notes on Theorem 7, see the following.

- The region $\mathcal{R}^{(\mathcal{D})}$ is convex. The proof is omitted here.
- The ranges of the random variables U, U_1, U_2 and V satisfy

$$\begin{gathered}
\|\mathcal{U}\| \leq \|\mathcal{X}_1\| \|\mathcal{X}_2\| + 1, \\
\|\mathcal{U}_1\| \leq \|\mathcal{X}_1\| \|\mathcal{X}_2\|, \\
\|\mathcal{U}_2\| \leq \|\mathcal{X}_1\| \|\mathcal{X}_2\|, \\
\|\mathcal{V}\| \leq (\|\mathcal{X}_1\| \|\mathcal{X}_2\| + 1)^2 \|\mathcal{X}_1\|^2 \|\mathcal{X}_2\|^2.
\end{gathered}$$

  The proof is in Appendix G.
- The secrecy capacity region $\mathcal{C}_s^{(D)}$ is the set of pairs (R_1, R_2) such that $(R_1, R_2, R_e = R_1 + R_2) \in \mathcal{R}^{(\mathcal{D})}$.

  Corollary 7:

$$\begin{aligned}
&\mathcal{C}_s^{(D)} = \{(R_1, R_2) : R_1 \leq I(V; Y | U_2), \\
&R_2 \leq I(V; Y | U_1), \\
&R_1 + R_2 \leq I(V; Y | U) - I(V; Z | U)\}.
\end{aligned}$$

Proof: Corollary 7 is easy to be checked by substituting $R_e = R_1 + R_2$ into $\mathcal{R}^{(\mathcal{D})}$. ■

For the degraded MAC-WT with cooperative encoders, i.e., $(W_1, W_2) \rightarrow (X_1, X_2) \rightarrow Y \rightarrow Z$**, the capacity-equivocation region** $\mathcal{R}^{(\mathcal{E})}$ **is given in the following Theorem 8, and it is proved in Appendix H.**

Theorem 8: A single-letter characterization of the region $\mathcal{R}^{(\mathcal{E})}$ for the degraded MAC-WT with cooperative encoders is as follows,

$$\mathcal{R}^{(\mathcal{E})} = \{(R_1, R_2, R_e) : R_e \leq R_1 + R_2,$$

$$0 \leq R_1 \leq I(V;Y|U_2),$$

$$0 \leq R_2 \leq I(V;Y|U_1),$$

$$R_1 + R_2 \leq I(V;Y),$$

$$R_e \leq I(V;Y) - I(V;Z)\},$$

where $(U_1, U_2) \rightarrow V \rightarrow (X_1, X_2) \rightarrow (Y, Z)$, and U_1, U_2 may be assumed to be (deterministic) functions of V.

Remark 4: There are some notes on Theorem 8, see the following.

- For the degraded case, the last bound in Theorem 8 can be obtained from the corresponding bound of Theorem 7, see the following.

$$\begin{aligned} R_e &\leq I(V;Y|U) - I(V;Z|U) \\ &= I(V;Y) - I(V;Z) - (I(U;Y) - I(U;Z)) \\ &\leq I(V;Y) - I(V;Z). \end{aligned} \tag{4.3}$$

  Therefore, the converse proof of Theorem 8 is directly obtained from that of Theorem 7 and the above (4.3).
- The region $\mathcal{R}^{(\mathcal{E})}$ is convex. The proof is omitted here.
- The ranges of the random variables U_1, U_2 and V satisfy

$$\|\mathcal{U}_1\| \leq \|\mathcal{X}_1\|\|\mathcal{X}_2\|,$$

$$\|\mathcal{U}_2\| \leq \|\mathcal{X}_1\|\|\mathcal{X}_2\|,$$

$$\|\mathcal{V}\| \leq (\|\mathcal{X}_1\|\|\mathcal{X}_2\| + 1)\|\mathcal{X}_1\|^2\|\mathcal{X}_2\|^2.$$

  The proof is similar to Appendix G, and it is omitted here.
- The secrecy capacity region $\mathcal{C}_s^{(E)}$ is the set of pairs (R_1, R_2) such that $(R_1, R_2, R_e = R_1 + R_2) \in \mathcal{R}^{(\mathcal{E})}$.

  Corollary 8:

$$\mathcal{C}_s^{(E)} = \{(R_1, R_2) : R_1 \leq I(V;Y|U_2),$$

$$R_2 \leq I(V;Y|U_1),$$

$$R_1 + R_2 \leq I(V;Y) - I(V;Z)\}.$$

Proof: Corollary 8 is easy to be checked by substituting $R_e = R_1 + R_2$ into $\mathcal{R}^{(\mathcal{E})}$ ■

V. DEGRADED MULTIPLE ACCESS WIRETAP CHANNEL WITH NON-COOPERATIVE ENCODERS

In this section, we will present inner and outer bounds on the capacity-equivocation of the degraded MAC-WT with non-cooperative encoders. For the non-cooperative model, the input of encoder 1 is W_1, while the output of encoder 1 is X_1^N. Similarly, the input and output of encoder 2 are W_2 and X_2^N, respectively. The encoders are stochastic encoders, i.e., the encoder g_i^{*N} $(i = 1, 2)$ is a matrix of conditional probabilities $g_i^{*N}(x_i^N|w_i)$, where $x_i^N \in \mathcal{X}_i^N$, $w_i \in \mathcal{W}_i$, and $g_i^{*N}(x_i^N|w_i)$ is the probability that the message w_i is encoded as the channel input x_i^N. Note that X_1^N and X_2^N are independent.

The inner and outer bounds on the capacity-equivocation region $\mathcal{R}^{(\mathcal{F})}$ of the degraded MAC-WT with non-cooperative encoders are provided in Theorem 9 and Theorem 10, respectively, and they are proved in Appendix I and Appendix J.

Theorem 9: (**Inner bound**) A single-letter characterization of the region $\mathcal{R}^{(\mathcal{G})}$ is as follows,

$$\mathcal{R}^{(\mathcal{G})} = \mathcal{L}^{(1)} \bigcup \mathcal{L}^{(2)} \bigcup \mathcal{L}^{(3)} \bigcup \mathcal{L}^{(4)},$$

where

$$\mathcal{L}^{(1)} = \left\{ \begin{array}{l} (R_1, R_2, R_e): \\ R_1 \le I(X_1;Y) - I(X_1;Z) \\ R_2 \le I(X_2;Y|X_1) \\ R_1 + R_2 \le I(X_1, X_2;Y) \\ R_e \le R_1 + R_2 \\ R_e \le I(X_2;Y|X_1) - I(X_2;Z|X_1) + R_1 \end{array} \right\},$$

$$\mathcal{L}^{(2)} = \left\{ \begin{array}{l} (R_1, R_2, R_e): \\ R_1 \le I(X_1;Y|X_2) \\ R_2 \le I(X_2;Y) - I(X_2;Z) \\ R_1 + R_2 \le I(X_1, X_2;Y) \\ R_e \le R_1 + R_2 \\ R_e \le I(X_1;Y|X_2) - I(X_1;Z|X_2) + R_2 \end{array} \right\},$$

$$\mathcal{L}^{(3)} = \left\{ \begin{array}{l} (R_1, R_2, R_e): \\ I(X_1;Y) - I(X_1;Z) \le R_1 \le I(X_1;Y) \\ I(X_2;Y|X_1) - I(X_2;Z|X_1) \le R_2 \le I(X_2;Y|X_1) \\ R_1 + R_2 \le I(X_1, X_2;Y) \\ R_e \le R_1 + R_2 \\ R_e \le I(X_1, X_2;Y) - I(X_1, X_2;Z) \end{array} \right\},$$

$$\mathcal{L}^{(4)} = \left\{ \begin{array}{l} (R_1, R_2, R_e): \\ I(X_1;Y|X_2) - I(X_1;Z|X_2) \leq R_1 \leq I(X_1;Y|X_2) \\ I(X_2;Y) - I(X_2;Z) \leq R_2 \leq I(X_2;Y) \\ R_1 + R_2 \leq I(X_1, X_2; Y) \\ R_e \leq R_1 + R_2 \\ R_e \leq I(X_1, X_2; Y) - I(X_1, X_2; Z) \end{array} \right\},$$

and X_1, X_2, Y and Z satisfy $(X_1, X_2) \rightarrow Y \rightarrow Z$, and $\mathcal{R}^{(\mathcal{G})} \subseteq \mathcal{R}^{(\mathcal{F})}$.

Remark 5: There are some notes on Theorem 9, see the following.

- The region $\mathcal{R}^{(\mathcal{G})}$ is convex. The proof is omitted here.
- The secrecy capacity region $\mathcal{C}_s^{(F)}$ is the set of pairs (R_1, R_2) such that $(R_1, R_2, R_e = R_1 + R_2) \in \mathcal{R}^{(\mathcal{F})}$.

Corollary 9: (**Inner bound on secrecy capacity region**) The secrecy capacity region $\mathcal{C}_s^{(F)}$ satisfies $\mathcal{C}_s^{(G)} \subseteq \mathcal{C}_s^{(F)}$, where

$$\mathcal{C}_s^{(G)} = \left\{ \begin{array}{l} (R_1, R_2): \\ R_1 \leq I(X_1;Y) - I(X_1;Z) \\ R_2 \leq I(X_2;Y|X_1) - I(X_2;Z|X_1) \end{array} \right\} \bigcup \left\{ \begin{array}{l} (R_1, R_2): \\ R_1 \leq I(X_1;Y|X_2) - I(X_1;Z|X_2) \\ R_2 \leq I(X_2;Y) - I(X_2;Z) \end{array} \right\}.$$

Proof: Corollary 9 is easy to be checked by substituting $R_e = R_1 + R_2$ into $\mathcal{R}^{(\mathcal{G})}$. ■

Theorem 10: (**Outer bound**) A single-letter characterization of the region $\mathcal{R}^{(\mathcal{H})}$ is as follows,

$$\mathcal{R}^{(\mathcal{H})} = \left\{ \begin{array}{l} (R_1, R_2, R_e): \\ R_1 \leq I(X_1;Y|X_2) \\ R_2 \leq I(X_2;Y|X_1) \\ R_1 + R_2 \leq I(X_1, X_2; Y) \\ R_e \leq R_1 + R_2 \\ R_e \leq I(X_1, X_2; Y) - I(X_1, X_2; Z) \end{array} \right\},$$

where X_1, X_2, Y and Z satisfy $(X_1, X_2) \rightarrow Y \rightarrow Z$, and $\mathcal{R}^{(\mathcal{F})} \subseteq \mathcal{R}^{(\mathcal{H})}$.

Remark 6: There are some notes on Theorem 10, see the following.

- The region $\mathcal{R}^{(\mathcal{H})}$ is convex. The proof is omitted here.
- *Corollary 10:* (**Outer bound on secrecy capacity region**) The secrecy capacity region $\mathcal{C}_s^{(F)}$ satisfies $\mathcal{C}_s^{(F)} \subseteq \mathcal{C}_s^{(H)}$, where

$$\mathcal{C}_s^{(H)} = \left\{ \begin{array}{l} (R_1, R_2): \\ R_1 \leq I(X_1;Y|X_2) \\ R_2 \leq I(X_2;Y|X_1) \\ R_1 + R_2 \leq I(X_1, X_2; Y) - I(X_1, X_2; Z) \end{array} \right\}.$$

Proof: Corollary 10 is easy to be checked by substituting $R_e = R_1 + R_2$ into $\mathcal{R}^{(\mathcal{H})}$. ■

VI. BINARY DEGRADED MAC-WT WITH COOPERATIVE (OR NON-COOPERATIVE) ENCODERS

A. The Binary Case of the Degraded MAC-WT with Cooperative Encoders

In this subsection, we study the binary case of the degraded MAC-WT with cooperative encoders. Assume that all channel inputs and outputs take values in $\{0,1\}$, and the channels are discrete memoryless. The input-output relationship of the channels at each time instant satisfies

$$Y_i = X_{1,i} \cdot X_{2,i}, \quad Z_i = Y_i \oplus Z_i^*, \tag{6.1}$$

where $1 \leq i \leq N$, and Z^{*N} is composed of N i.i.d. random variables with distribution $Pr\{Z_i^* = 1\} = p$ and $Pr\{Z_i^* = 0\} = 1 - p$. Let $0 \leq p \leq \frac{1}{2}$.

Theorem 11: For the binary case of the degraded MAC-WT with cooperative encoders, the capacity-equivocation region $\mathcal{R}^{(\mathcal{I})}$ is given by

$$\mathcal{R}^{(\mathcal{I})} = \left\{ (R_1, R_2, R_e) : \begin{array}{l} 0 \leq R_1 \leq 1 \\ 0 \leq R_2 \leq 1 \\ R_1 + R_2 \leq 1 \\ R_e \leq R_1 + R_2 \\ R_e \leq h(p) \end{array} \right\}, \tag{6.2}$$

where $h(p) = -p\log(p) - (1-p)\log(1-p)$.

Proof: By calculating the mutual information terms in Theorem 8, Theorem 11 is easy to be checked, and therefore, the proof is omitted here. ■

Corollary 11: The secrecy capacity region of the binary case of the degraded MAC-WT with cooperative encoders is

$$\mathcal{C}_s^{(I)} = \left\{ (R_1, R_2) : \begin{array}{l} R_1 + R_2 \leq h(p) \\ R_1 \leq 1 \\ R_2 \leq 1 \end{array} \right\}. \tag{6.3}$$

Proof: Substituting $R_e = R_1 + R_2$ into the region $\mathcal{R}^{(\mathcal{I})}$ in Theorem 11, Corollary 11 is easily obtained. ■

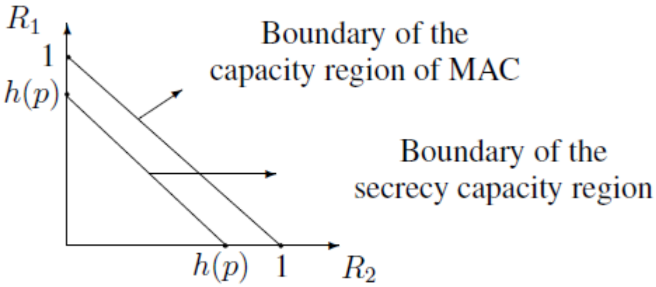

Fig. 8: The secrecy capacity region of the binary case of the degraded MAC-WT with cooperative encoders, and the capacity region of the binary MAC

Figure 8 shows the secrecy capacity region of the binary case of the degraded MAC-WT with cooperative encoders, and the capacity region of the binary MAC. It is easy to see that as $p \to \frac{1}{2}$, the secrecy capacity region tends to be the capacity region of the binary MAC.

B. The Binary Case of the Degraded MAC-WT with Non-Cooperative Encoders

In this subsection, we study the binary case of the degraded MAC-WT with non-cooperative encoders. Assume that all channel inputs and outputs take values in $\{0, 1\}$, and the channels are discrete memoryless. The input-output relationship of the channels at each time instant satisfies

$$Y_i = X_{1,i} \cdot X_{2,i}, \quad Z_i = Y_i \oplus Z_i^*, \tag{6.4}$$

where $1 \leq i \leq N$, and Z^{*N} is composed of N i.i.d. random variables with distribution $Pr\{Z_i^* = 1\} = p$ and $Pr\{Z_i^* = 0\} = 1 - p$. Let $0 \leq p \leq \frac{1}{2}$.

Theorem 12: For the binary case of the degraded MAC-WT with non-cooperative encoders, the inner bound on the secrecy capacity region is coincident with the corresponding outer bound. Therefore, the secrecy capacity region

$\mathcal{R}^{(\mathcal{J})}$ is

$$\mathcal{R}^{(\mathcal{J})} = \left\{ (R_1, R_2) : \begin{array}{c} 0 \leq R_1 \leq h(p) \\ 0 \leq R_2 \leq h(p) \\ R_1 + R_2 \leq h(p) \end{array} \right\}, \tag{6.5}$$

where $h(p) = -p\log(p) - (1-p)\log(1-p)$.

Proof: See Appendix K. ■

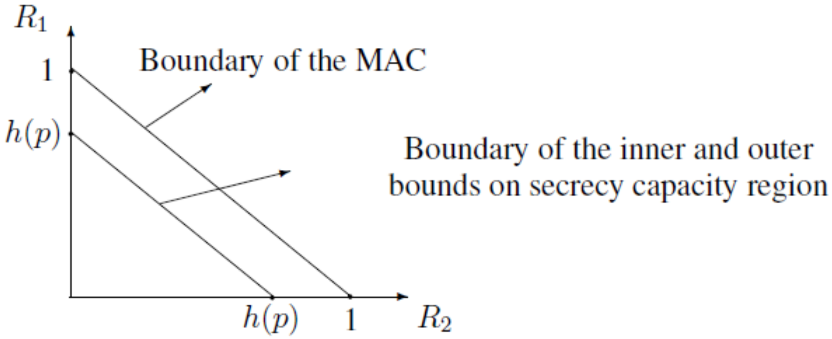

Fig. 9: The secrecy capacity region of the binary case of the degraded MAC-WT with non-cooperative encoders, and the capacity region of the binary MAC

Figure 9 shows the secrecy capacity region of the binary case of the degraded MAC-WT with non-cooperative encoders, and the capacity region of the binary MAC. It is easy to see that as $p \rightarrow \frac{1}{2}$, the secrecy capacity region tends to be the capacity region of the binary MAC.

VII. CONCLUSION

In this paper, first, we study the model of degraded MAC with confidential messages. The inner and outer bounds on the capacity-equivocation region and the secrecy capacity region are provided for this model. Second, as two examples, the binary and Gaussian cases of the degraded MAC with confidential messages are studied, and the inner and outer bounds on the capacity-equivocation regions are also given for the two examples.

Third, we investigate the MAC-WT with cooperative encoders. The capacity-equivocation regions and the corresponding secrecy capacity regions are determined for both the general model and the degraded model. Fourth, for the model of degraded MAC-WT with non-cooperative encoders, we present inner and outer bounds on the capacity-equivocation region. Finally, we give binary examples for the degraded MAC-WT with cooperative (or non-cooperative) encoders.

APPENDIX A

PROOF OF THEOREM 1

Suppose $(R_1, R_2, R_{e1}, R_{e2}) \in \mathcal{R}^{Ai}$, we will show that $(R_1, R_2, R_{e1}, R_{e2})$ is achievable. Without loss of generality, the proof of Theorem 1 is considered into the following four cases.

- **(Case 1)** If $I(X_2; Y) \geq I(X_2; Y_1|X_1)$ and $R_2 \leq I(X_2; Y)$, we only need to prove that the tuple $(R_0, R_1, R_{e1}, R_{e2})$ satisfying $R_{e1} = I(X_1; Y|X_2) - I(X_1; Y_2|X_2)$ and $R_{e2} = I(X_2; Y) - I(X_2; Y_1|X_1)$, is achievable.
- **(Case 2)** If $I(X_2; Y) \geq I(X_2; Y_1|X_1)$ and $R_2 \geq I(X_2; Y)$, we only need to prove that the tuple $(R_0, R_1, R_{e1}, R_{e2})$ satisfying $R_{e1} = I(X_1; Y|X_2) - I(X_1; Y_2|X_2) + I(X_2; Y) - R_2$ and $R_{e2} = I(X_2; Y) - I(X_2; Y_1|X_1)$ is achievable.
- **(Case 3)** If $I(X_2; Y) \leq I(X_2; Y_1|X_1)$ and $R_2 \leq I(X_2; Y_1|X_1)$, we only need to prove that the tuple $(R_0, R_1, R_{e1}, R_{e2})$ satisfying $R_{e1} = I(X_1; Y|X_2) - I(X_1; Y_2|X_2) + I(X_2; Y) - I(X_2; Y_1|X_1)$ and $R_{e2} = 0$ is achievable.
- **(Case 4)** If $I(X_2; Y) \leq I(X_2; Y_1|X_1)$ and $R_2 \geq I(X_2; Y_1|X_1)$, we only need to prove that the tuple $(R_0, R_1, R_{e1}, R_{e2})$ satisfying $R_{e1} = I(X_1; Y|X_2) - I(X_1; Y_2|X_2) + I(X_2; Y) - R_2$ and $R_{e2} = 0$ is achievable.

Now the remainder of this section is organized as follows. Some preliminaries about typical sequences are introduced in Subsection A-A. For the four cases, the construction of the code is introduced in Subsection A-B. For any given $\epsilon > 0$, the proofs of $\lim_{N\to\infty} \frac{\log\|\mathcal{W}_1\|}{N} = R_1$, $\lim_{N\to\infty} \frac{\log\|\mathcal{W}_2\|}{N} = R_2$, $\lim_{N\to\infty} \Delta_1 \geq R_{e1}$, $\lim_{N\to\infty} \Delta_2 \geq R_{e2}$ and $P_e \leq \epsilon$ are given in Subsection A-C.

A. Preliminaries

- Given a probability mass function $p_V(v)$, for any $\eta > 0$, let $T_V^N(\eta)$ be the strong typical set of all v^N such that $|p_V(v) - \frac{c_{v^N}(v)}{N}| < \eta$ for all $v \in \mathcal{V}$, where $c_{v^N}(v)$ is the number of occurences of the letter v in the v^N. We say that the sequences $v^N \in T_V^N(\eta)$ are V**-typical**.
- Analogously, given a joint probability mass function $p_{VW}(v, w)$, for any $\eta > 0$, let $T_{VW}^N(\eta)$ be the joint strong typical set of all pairs (v^N, w^N) such that $|p_{VW}(v, w) - \frac{c_{v^N,w^N}(v,w)}{N}| < \eta$ for all $v \in \mathcal{V}$ and $w \in \mathcal{W}$, where $c_{v^N,w^N}(v, w)$ is the number of occurences of (v, w) in the pair of sequences (v^N, w^N). We say that the pairs of sequences $(v^N, w^N) \in T_{VW}^N(\eta)$ are VW**-typical**.
- Moreover, w^N is called $W|V$**-generated** by v^N iff v^N is V- typical and $(v^N, w^N) \in T_{VW}^N(\eta)$. For any given $v^N \in T_V^N(\eta)$, define $T_{W|V}^N(\eta) = \{w^N : w^N \text{ is } W|V\text{-generated by } v^N\}$.
- *Lemma 1:* For any $v^N \in T_V^N(\eta)$,

  $$2^{-N(H(V)+\eta^*)} \leq p_{V^N}(v^N) \leq 2^{-N(H(V)-\eta^*)},$$

  where $\eta^* \to 0$ as $\eta \to 0$.

B. Coding Construction

The code constructions for the four cases are almost the same (by using Wyner's random binning technique), except that the total number of x_1^N and x_2^N are different, see the followings.

- For case 1, the existence of the encoder-decoder is under the sufficient conditions that $R_{e1} = I(X_1;Y|X_2) - I(X_1;Y_2|X_2)$ and $R_{e2} = I(X_2;Y) - I(X_2;Y_1|X_1)$. Given a tuple $(R_1, R_2, R_{e1}, R_{e2})$, choose a joint probability mass function $p_{X_1,X_2,Y,Y_1,Y_2}(x_1, x_2, y, y_1, y_2)$ such that

  $$0 \leq R_1 \leq I(X_1;Y|X_2), \quad 0 \leq R_2 \leq I(X_2;Y|X_1), \quad R_1 + R_2 \leq I(X_1, X_2;Y),$$

  $$R_{e1} \leq R_1, \quad R_{e1} = I(X_1;Y|X_2) - I(X_1;Y_2|X_2),$$

  $$R_{e2} \leq R_2, \quad R_{e2} = I(X_2;Y) - I(X_2;Y_1|X_1).$$

  It is easy to check that the last three inequalities in Theorem 1 hold by using the conditions that $R_{e1} = I(X_1;Y|X_2) - I(X_1;Y_2|X_2)$ and $R_{e2} = I(X_2;Y) - I(X_2;Y_1|X_1)$.

  The confidential message sets $\mathcal{W}_1$ and $\mathcal{W}_2$ satisfy the following conditions:

  $$\lim_{N\to\infty} \frac{1}{N} \log \parallel \mathcal{W}_1 \parallel = R_1, \quad \lim_{N\to\infty} \frac{1}{N} \log \parallel \mathcal{W}_2 \parallel = R_2. \tag{6}$$

  Code-book generation for case 1:

  - Generate $2^{N(I(X_1;Y|X_2)-\epsilon_N)}$ codewords x_1^N ($\epsilon_N \to \infty$ as $N \to \infty$), and each of them is uniformly drawn from the strong typical set $T_{X_1}^N(\eta)$. Divide the $2^{N(I(X_1;Y|X_2)-\epsilon_N)}$ codewords into 2^{NR_1} bins, and each bin corresponds to a specific value in $\mathcal{W}_1$.
  - Analogously, generate $2^{N(I(X_2;Y)-\epsilon_N)}$ codewords x_2^N, and each of them is uniformly drawn from the strong typical set $T_{X_2}^N(\eta)$. Divide the $2^{N(I(X_2;Y)-\epsilon_N)}$ codewords into 2^{NR_2} bins, and each bin corresponds to a specific value in $\mathcal{W}_2$.

- For case 2, the existence of the encoder-decoder is under the sufficient conditions that $R_{e1} = I(X_1;Y|X_2) - I(X_1;Y_2|X_2) + I(X_2;Y) - R_2$ and $R_{e2} = I(X_2;Y) - I(X_2;Y_1|X_1)$. Given a tuple $(R_1, R_2, R_{e1}, R_{e2})$, choose a joint probability mass function $p_{X_1,X_2,Y,Y_1,Y_2}(x_1, x_2, y, y_1, y_2)$ such that

  $$0 \leq R_1 \leq I(X_1;Y|X_2), \quad 0 \leq R_2 \leq I(X_2;Y|X_1), \quad R_1 + R_2 \leq I(X_1, X_2;Y),$$

  $$R_{e1} \leq R_1, \quad R_{e1} = I(X_1;Y|X_2) - I(X_1;Y_2|X_2) + I(X_2;Y) - R_2,$$

  $$R_{e2} \leq R_2, \quad R_{e2} = I(X_2;Y) - I(X_2;Y_1|X_1).$$

  It is easy to check that the last three inequalities in Theorem 1 hold by using the conditions that $R_{e1} = I(X_1;Y|X_2) - I(X_1;Y_2|X_2) + I(X_2;Y) - R_2$ and $R_{e2} = I(X_2;Y) - I(X_2;Y_1|X_1)$.

  The confidential message sets $\mathcal{W}_1$ and $\mathcal{W}_2$ also satisfy (6).

  Code-book generation for case 2:

- Generate $2^{N(I(X_1;Y|X_2)+I(X_2;Y)-R_2-\epsilon_N)}$ codewords x_1^N ($\epsilon_N \to \infty$ as $N \to \infty$), and each of them is uniformly drawn from the strong typical set $T^N_{X_1}(\eta)$. Divide the $2^{N(I(X_1;Y|X_2)+I(X_2;Y)-R_2-\epsilon_N)}$ codewords into 2^{NR_1} bins, and each bin corresponds to a specific value in $\mathcal{W}_1$.
- Generate $2^{N(I(X_2;Y)-\epsilon_N)}$ codewords x_2^N, and each of them is uniformly drawn from the strong typical set $T^N_{X_2}(\eta)$. Divide the $2^{N(I(X_2;Y)-\epsilon_N)}$ codewords into 2^{NR_2} bins, and each bin corresponds to a specific value in $\mathcal{W}_2$.

- For case 3, the existence of the encoder-decoder is under the sufficient conditions that $R_{e1} = I(X_1;Y|X_2) - I(X_1;Y_2|X_2) + I(X_2;Y) - I(X_2;Y_1|X_1)$ and $R_{e2} = 0$. Given a tuple $(R_1, R_2, R_{e1}, R_{e2})$, choose a joint probability mass function $p_{X_1,X_2,Y,Y_1,Y_2}(x_1, x_2, y, y_1, y_2)$ such that

$$0 \le R_1 \le I(X_1;Y|X_2), \quad 0 \le R_2 \le I(X_2;Y|X_1), \quad R_1 + R_2 \le I(X_1, X_2;Y),$$

$$R_{e1} \le R_1, \quad R_{e1} = I(X_1;Y|X_2) - I(X_1;Y_2|X_2) + I(X_2;Y) - I(X_2;Y_1|X_1),$$

$$R_{e2} \le R_2, \quad R_{e2} = 0.$$

It is easy to check that the last three inequalities in Theorem 1 hold by using the conditions that $R_{e1} = I(X_1;Y|X_2) - I(X_1;Y_2|X_2) + I(X_2;Y) - I(X_2;Y_1|X_1)$ and $R_{e2} = 0$.

The confidential message sets $\mathcal{W}_1$ and $\mathcal{W}_2$ also satisfy (6).

Code-book generation for case 3:

- Generate $2^{N(I(X_1;Y|X_2)+I(X_2;Y)-I(X_2;Y_1|X_1)-\epsilon_N)}$ codewords x_1^N ($\epsilon_N \to \infty$ as $N \to \infty$), and each of them is uniformly drawn from the strong typical set $T^N_{X_1}(\eta)$. Divide the $2^{N(I(X_1;Y|X_2)+I(X_2;Y)-I(X_2;Y_1|X_1)-\epsilon_N)}$ codewords into 2^{NR_1} bins, and each bin corresponds to a specific value in $\mathcal{W}_1$.
- Generate $2^{N(I(X_2;Y)-\epsilon_N)}$ codewords x_2^N, and each of them is uniformly drawn from the strong typical set $T^N_{X_2}(\eta)$. Divide the $2^{N(I(X_2;Y)-\epsilon_N)}$ codewords into 2^{NR_2} bins, and each bin corresponds to a specific value in $\mathcal{W}_2$.

- For case 4, the existence of the encoder-decoder is under the sufficient conditions that $R_{e1} = I(X_1;Y|X_2) - I(X_1;Y_2|X_2) + I(X_2;Y) - R_2$ and $R_{e2} = 0$. Given a tuple $(R_1, R_2, R_{e1}, R_{e2})$, choose a joint probability mass function $p_{X_1,X_2,Y,Y_1,Y_2}(x_1, x_2, y, y_1, y_2)$ such that

$$0 \le R_1 \le I(X_1;Y|X_2), \quad 0 \le R_2 \le I(X_2;Y|X_1), \quad R_1 + R_2 \le I(X_1, X_2;Y),$$

$$R_{e1} \le R_1, \quad R_{e1} = I(X_1;Y|X_2) - I(X_1;Y_2|X_2) + I(X_2;Y) - R_2,$$

$$R_{e2} \le R_2, \quad R_{e2} = 0.$$

It is easy to check that the last three inequalities in Theorem 1 hold by using the conditions that $R_{e1} = I(X_1;Y|X_2) - I(X_1;Y_2|X_2) + I(X_2;Y) - R_2$ and $R_{e2} = 0$.

The confidential message sets $\mathcal{W}_1$ and $\mathcal{W}_2$ also satisfy (6).

Code-book generation for case 4:

  - Generate $2^{N(I(X_1;Y|X_2)+I(X_2;Y)-R_2-\epsilon_N)}$ codewords x_1^N ($\epsilon_N \to \infty$ as $N \to \infty$), and each of them is uniformly drawn from the strong typical set $T_{X_1}^N(\eta)$. Divide the $2^{N(I(X_1;Y|X_2)+I(X_2;Y)-R_2-\epsilon_N)}$ codewords into 2^{NR_1} bins, and each bin corresponds to a specific value in $\mathcal{W}_1$.
  - Generate $2^{N(I(X_2;Y)-\epsilon_N)}$ codewords x_2^N, and each of them is uniformly drawn from the strong typical set $T_{X_2}^N(\eta)$. Divide the $2^{N(I(X_2;Y)-\epsilon_N)}$ codewords into 2^{NR_2} bins, and each bin corresponds to a specific value in $\mathcal{W}_2$.

- **(Decoding scheme for all cases)** For a given y^N, try to find a pair of sequences $(x_1^N(\hat{w}_1), x_2^N(\hat{w}_2))$ such that $(x_1^N(\hat{w}_1), x_2^N(\hat{w}_2), y^N) \in T_{X_1X_2Y}^N(\epsilon)$. If there exist sequences with the same indices $\hat{w}_1$ and $\hat{w}_2$, put out the corresponding $\hat{w}_1$ and $\hat{w}_2$, else declare a decoding error.

C. *Proof of the Achievability*

By using the above definitions, it is easy to verify that $\lim_{N\to\infty} \frac{\log\|\mathcal{W}_1\|}{N} = R_1$ and $\lim_{N\to\infty} \frac{\log\|\mathcal{W}_2\|}{N} = R_2$ for the two cases.

From the standard techniques as in [18, Ch. 14], we have $P_e \le \epsilon$ for all cases.

It remains to show that $\lim_{N\to\infty} \Delta_1 \ge R_{e1}$ and $\lim_{N\to\infty} \Delta_2 \ge R_{e2}$ for the four cases, see the followings.

- **(Proof of $\lim_{N\to\infty} \Delta_1 \ge R_{e1}$ and $\lim_{N\to\infty} \Delta_2 \ge R_{e2}$ for case 1)**

  First, we compute the following equivocation rate of W_1.

$$\begin{aligned}
\lim_{N\to\infty} \Delta_1 &\triangleq \lim_{N\to\infty} \frac{1}{N} H(W_1|Y_2^N, X_2^N) \\
&= \lim_{N\to\infty} \frac{1}{N} (H(W_1, Y_2^N, X_2^N) - H(Y_2^N, X_2^N)) \\
&= \lim_{N\to\infty} \frac{1}{N} (H(W_1, Y_2^N, X_1^N, X_2^N) - H(X_1^N|W_1, Y_2^N, X_2^N) - H(Y_2^N, X_2^N)) \\
&\overset{(a)}{=} \lim_{N\to\infty} \frac{1}{N} (H(Y_2^N|X_1^N, X_2^N) + H(W_1, X_1^N) + H(X_2^N) - H(X_1^N|W_1, Y_2^N, X_2^N) \\
&\quad - H(Y_2^N, X_2^N)) \\
&= \lim_{N\to\infty} \frac{1}{N} (H(Y_2^N|X_1^N, X_2^N) + H(X_1^N|W_1) + H(W_1) - H(X_1^N|W_1, Y_2^N, X_2^N) \\
&\quad - H(Y_2^N|X_2^N)) \\
&= \lim_{N\to\infty} \frac{1}{N} (H(X_1^N|W_1) + H(W_1) - H(X_1^N|W_1, Y_2^N, X_2^N) - I(Y_2^N; X_1^N|X_2^N),
\end{aligned} \tag{7}$$

  where (a) is from $W_1 \to (X_1^N, X_2^N) \to Y_2^N$ and the fact that X_2^N is independent of W_1 and X_1^N.

  The first term in (7) can be bounded as follows.

$$\lim_{N\to\infty} \frac{1}{N} H(X_1^N|W_1) \ge I(X_1; Y|X_2) - R_1, \tag{8}$$

  where (8) is from the property of the strong typical sequences.

  The second term in (7) is as follows.

$$\lim_{N\to\infty} \frac{1}{N} H(W_1) = R_1. \tag{9}$$

For the third term in (7), we have

$$\lim_{N\to\infty}\frac{1}{N}H(X_1^N|W_1,Y_2^N,X_2^N)=0. \tag{10}$$

This is because for a given w_1, there are $2^{N(I(X_1;Y|X_2)-\epsilon_N-R_1)}$ codewords left for x_1^N. Then note that

$$\begin{aligned}I(X_1;Y|X_2)-\epsilon_N-R_1 &\leq I(X_1;Y|X_2)-\epsilon_N-R_{e1}\\ &= I(X_1;Y|X_2)-\epsilon_N-(I(X_1;Y|X_2)-I(X_1;Y_2|X_2))\\ &= I(X_1;Y_2|X_2)-\epsilon_N,\end{aligned}$$

and $\epsilon_N\to 0$ as $N\to\infty$. From the standard channel coding theorem and the Fano's inequality, we have (10).

For the fourth term in (7), we have

$$\lim_{N\to\infty}\frac{1}{N}I(Y_2^N;X_1^N|X_2^N)\leq I(X_1;Y_2|X_2), \tag{11}$$

and this is from a standard technique as in [2, p. 343].

Substituting (8), (9), (10) and (11) into (7), we have

$$\lim_{N\to\infty}\Delta_1\geq I(X_1;Y|X_2)-I(X_1;Y_2|X_2)=R_{e1}. \tag{12}$$

$\lim_{N\to\infty}\Delta_1\geq R_{e1}$ is proved. Analogously, we can prove that $\lim_{N\to\infty}\Delta_2\geq R_{e2}$, see the following.

$$\begin{aligned}\lim_{N\to\infty}\Delta_2 &\triangleq \lim_{N\to\infty}\frac{1}{N}H(W_2|Y_1^N,X_1^N)\\ &= \lim_{N\to\infty}\frac{1}{N}(H(W_2,Y_1^N,X_1^N)-H(Y_1^N,X_1^N))\\ &= \lim_{N\to\infty}\frac{1}{N}(H(W_2,Y_1^N,X_2^N,X_1^N)-H(X_2^N|W_2,Y_1^N,X_1^N)-H(Y_1^N,X_1^N))\\ &\overset{(a)}{=} \lim_{N\to\infty}\frac{1}{N}(H(Y_1^N|X_2^N,X_1^N)+H(W_2,X_2^N)+H(X_1^N)-H(X_2^N|W_2,Y_1^N,X_1^N)\\ &\quad -H(Y_1^N,X_1^N))\\ &= \lim_{N\to\infty}\frac{1}{N}(H(Y_1^N|X_2^N,X_1^N)+H(X_2^N|W_2)+H(W_2)-H(X_2^N|W_2,Y_1^N,X_1^N)\\ &\quad -H(Y_1^N|X_1^N))\\ &= \lim_{N\to\infty}\frac{1}{N}(H(X_2^N|W_2)+H(W_2)-H(X_2^N|W_2,Y_1^N,X_1^N)-I(Y_1^N;X_2^N|X_1^N),\end{aligned} \tag{13}$$

where (a) is from $W_2\to(X_1^N,X_2^N)\to Y_1^N$ and the fact that X_1^N is independent of W_2 and X_2^N.

The first term in (13) can be bounded as follows.

$$\lim_{N\to\infty}\frac{1}{N}H(X_2^N|W_2)\geq I(X_2;Y)-R_2, \tag{14}$$

where (14) is from the property of the strong typical sequences.

The second term in (13) is as follows.

$$\lim_{N\to\infty}\frac{1}{N}H(W_2)=R_2. \tag{15}$$

For the third term in (13), we have

$$\lim_{N\to\infty}\frac{1}{N}H(X_2^N|W_2,Y_1^N,X_1^N)=0. \tag{16}$$

This is because for a given w_2, there are $2^{N(I(X_2;Y)-\epsilon_N-R_2)}$ codewords left for x_2^N. Then note that

$$\begin{aligned} I(X_2;Y)-\epsilon_N-R_2 &\le I(X_2;Y)-\epsilon_N-R_{e2} \\ &= I(X_2;Y)-\epsilon_N-(I(X_2;Y)-I(X_2;Y_1|X_1)) \\ &= I(X_2;Y_1|X_1)-\epsilon_N, \end{aligned}$$

and $\epsilon_N\to 0$ as $N\to\infty$. From the standard channel coding theorem and the Fano's inequality, we have (16).

For the fourth term in (13), we have

$$\lim_{N\to\infty}\frac{1}{N}I(Y_1^N;X_2^N|X_1^N)\le I(X_2;Y_1|X_1), \tag{17}$$

and this is from a standard technique as in [2, p. 343].

Substituting (14), (15), (16) and (17) into (13), we have

$$\lim_{N\to\infty}\Delta_2\ge I(X_2;Y)-I(X_2;Y_1|X_1)=R_{e2}. \tag{18}$$

$\lim_{N\to\infty}\Delta_2\ge R_{e2}$ is proved. Therefore, the proof for case 1 is completed.

- **(Proof of $\lim_{N\to\infty}\Delta_1\ge R_{e1}$ and $\lim_{N\to\infty}\Delta_2\ge R_{e2}$ for case 2, case 3 and case 4)** Note that (7) and (13) also hold for case 2, case 3 and case 4, and the proofs of $\lim_{N\to\infty}\Delta_1\ge R_{e1}$ and $\lim_{N\to\infty}\Delta_2\ge R_{e2}$ are similar to that of case 1. Therefore, we omit the proof here. The proof for case 2, case 3 and case 4 is completed.

The proof of Theorem 1 is completed.

APPENDIX B

PROOF OF THEOREM 2

In this section, we prove Theorem 2: all the achievable (R_1,R_2,R_{e1},R_{e2}) tuples are contained in the set $\mathcal{R}^{(Ao)}$, i.e., for any achievable tuple, there exist random variables X_1, X_2, Y, Y_1 and Y_2 such that the inequalities in Theorem 2 hold, and $(X_1,X_2)\to Y\to(Y_1,Y_2)$ forms a Markov chain. We will prove the inequalities of Theorem 2 in the remainder of this section.

(Proof of $0\le R_1\le I(X_1;Y|X_2)$) The proof of this inequality is as follows.

$$\begin{aligned} \frac{1}{N}H(W_1) &\overset{(a)}{\le} \frac{1}{N}(I(W_1;Y^N)+\delta(P_e)) \\ &\overset{(b)}{\le} \frac{1}{N}(I(X_1^N;Y^N)+\delta(P_e)) \\ &\overset{(c)}{\le} \frac{1}{N}(I(X_1^N;Y^N|X_2^N)+\delta(P_e)) \\ &\overset{(d)}{\le} \frac{1}{N}(\sum_{i=1}^{N}I(X_{1,i};Y_i|X_{2,i})+\delta(P_e)) \\ &\overset{(e)}{=} I(X_1;Y|X_2)+\frac{\delta(P_e)}{N}, \end{aligned} \tag{1}$$

where (a) is from the Fano's inequality, (b) is from the data processing theorem, (c) is from the fact that X_1^N and X_2^N are independent, (d) is from the discrete memoryless property of the channel, and (e) is from the definitions that $X_1 \triangleq (X_{1,J}, J)$, $X_2 \triangleq (X_{2,J}, J)$, $Y \triangleq Y_J$, where J is a random variable (uniformly distributed over $\{1, 2, ..., N\}$), and it is independent of $X_{1,i}$, $X_{2,i}$ and Y_i.

By using $P_e \leq \epsilon$, $R_1 = \lim_{N \to \infty} \frac{H(W_1)}{N}$ and (1), it is easy to see that $0 \leq R_1 \leq I(X_1; Y|X_2)$.

(Proof of $0 \leq R_2 \leq I(X_2; Y|X_1)$**)** The proof is similar to the proof of $0 \leq R_1 \leq I(X_1; Y|X_2)$, and it is omitted here.

(Proof of $0 \leq R_1 + R_2 \leq I(X_1, X_2; Y)$**)**

$$\begin{aligned}
\frac{1}{N}H(W_1, W_2) &\overset{(1)}{\leq} \frac{1}{N}(I(W_1, W_2; Y^N) + \delta(P_e)) \\
&\overset{(2)}{\leq} \frac{1}{N}(I(X_1^N, X_2^N; Y^N) + \delta(P_e)) \\
&\overset{(3)}{\leq} \frac{1}{N}(\sum_{i=1}^{N} I(X_{1,i}, X_{2,i}; Y_i) + \delta(P_e)) \\
&\overset{(4)}{=} I(X_1, X_2; Y) + \frac{\delta(P_e)}{N},
\end{aligned} \tag{2}$$

where (1) is from the Fano's inequality, (2) is from the data processing theorem, (3) is from the discrete memoryless property of the channel, and (4) is from the definitions that $X_1 \triangleq (X_{1,J}, J)$, $X_2 \triangleq (X_{2,J}, J)$, $Y \triangleq Y_J$.

By using $P_e \leq \epsilon$, $R_1 = \lim_{N \to \infty} \frac{H(W_1)}{N}$, $R_2 = \lim_{N \to \infty} \frac{H(W_2)}{N}$ and (2), it is easy to see that $0 \leq R_1 + R_2 \leq I(X_1, X_2; Y)$.

(Proof of $0 \leq R_{e1} \leq R_1$ **and** $0 \leq R_{e2} \leq R_2$**)** The two inequalities are obtained by the following equations.

$$R_{e1} \leq \lim_{N \to \infty} \frac{1}{N} H(W_1|Y_2^N, X_2^N) \leq \lim_{N \to \infty} \frac{1}{N} H(W_1) = R_1. \tag{3}$$

$$R_{e2} \leq \lim_{N \to \infty} \frac{1}{N} H(W_2|Y_1^N, X_1^N) \leq \lim_{N \to \infty} \frac{1}{N} H(W_2) = R_2. \tag{4}$$

(Proof of $R_{e1} \leq I(X_1; Y|X_2) - I(X_1; Y_2|X_2)$**)** The proof is obtained by the following (5), (6), and $P_e \leq \epsilon$.

$$\begin{aligned}
R_{e1} &\leq \lim_{N \to \infty} \frac{1}{N} H(W_1|Y_2^N, X_2^N) \\
&\overset{(a)}{\leq} \lim_{N \to \infty} \frac{1}{N}(H(W_1|Y_2^N, X_2^N) + \delta(P_e) - H(W_1|Y_2^N, X_2^N, Y^N)) \\
&= \lim_{N \to \infty} \frac{1}{N}(I(W_1; Y^N|Y_2^N, X_2^N) + \delta(P_e)) \\
&\leq \lim_{N \to \infty} \frac{1}{N}(H(Y^N|Y_2^N, X_2^N) - H(Y^N|Y_2^N, X_2^N, W_1, X_1^N) + \delta(P_e)) \\
&\overset{(b)}{=} \lim_{N \to \infty} \frac{1}{N}(H(Y^N|Y_2^N, X_2^N) - H(Y^N|Y_2^N, X_2^N, X_1^N) + \delta(P_e)) \\
&= \lim_{N \to \infty} \frac{1}{N}(I(Y^N; X_1^N|Y_2^N, X_2^N) + \delta(P_e)),
\end{aligned} \tag{5}$$

where (a) is from the Fano's inequality, and (b) is from $W_1 \to (Y_2^N, X_2^N, X_1^N) \to Y^N$.

$$
\begin{aligned}
I(Y^N;X_1^N|Y_2^N,X_2^N) &= H(X_1^N|Y_2^N,X_2^N)-H(X_1^N|Y_2^N,X_2^N,Y^N)\\
&\overset{(c)}{=} H(X_1^N|Y_2^N,X_2^N)-H(X_1^N|X_2^N,Y^N)\\
&= H(X_1^N|Y_2^N,X_2^N)-H(X_1^N|X_2^N,Y^N)-H(X_1^N|X_2^N)+H(X_1^N|X_2^N)\\
&= I(X_1^N;Y^N|X_2^N)-I(X_1^N;Y_2^N|X_2^N)\\
&= H(Y^N|X_2^N)-H(Y^N|X_1^N,X_2^N)-H(Y_2^N|X_2^N)+H(Y_2^N|X_1^N,X_2^N)\\
&= \sum_{i=1}^{N}(H(Y_i|Y^{i-1},X_2^N)-H(Y_i|X_{1,i},X_{2,i})-H(Y_{2,i}|Y_2^{i-1},X_2^N)+H(Y_{2,i}|X_{1,i},X_{2,i}))\\
&\leq \sum_{i=1}^{N}(H(Y_i|Y^{i-1},X_2^N)-H(Y_i|X_{1,i},X_{2,i})-H(Y_{2,i}|Y_2^{i-1},X_2^N,Y^{i-1})+H(Y_{2,i}|X_{1,i},X_{2,i}))\\
&\overset{(d)}{=} \sum_{i=1}^{N}(H(Y_i|Y^{i-1},X_2^N)-H(Y_i|X_{1,i},X_{2,i})-H(Y_{2,i}|X_2^N,Y^{i-1})+H(Y_{2,i}|X_{1,i},X_{2,i}))\\
&\overset{(e)}{=} \sum_{i=1}^{N}(H(Y_i|U_i,X_{2,i})-H(Y_i|X_{1,i},X_{2,i})-H(Y_{2,i}|U_i,X_{2,i})+H(Y_{2,i}|X_{1,i},X_{2,i}))\\
&= \sum_{i=1}^{N}(H(Y_i|U_i,X_{2,i})-H(Y_i|X_{1,i},X_{2,i})-H(Y_i|X_{2,i})+H(Y_i|X_{2,i})\\
&\quad -H(Y_{2,i}|U_i,X_{2,i})+H(Y_{2,i}|X_{1,i},X_{2,i})+H(Y_{2,i}|X_{2,i})-H(Y_{2,i}|X_{2,i}))\\
&= \sum_{i=1}^{N}(I(X_{1,i};Y_i|X_{2,i})-I(U_i;Y_i|X_{2,i})+I(U_i;Y_{2,i}|X_{2,i})-I(X_{1,i};Y_{2,i}|X_{2,i}))\\
&= \sum_{i=1}^{N}(I(X_{1,i};Y_i|X_{2,i})-I(X_{1,i};Y_{2,i}|X_{2,i})+H(U_i|X_{2,i},Y_i)-H(U_i|X_{2,i},Y_{2,i}))\\
&\overset{(f)}{=} \sum_{i=1}^{N}(I(X_{1,i};Y_i|X_{2,i})-I(X_{1,i};Y_{2,i}|X_{2,i})+H(U_i|X_{2,i},Y_i,Y_{2,i})-H(U_i|X_{2,i},Y_{2,i}))\\
&= \sum_{i=1}^{N}(I(X_{1,i};Y_i|X_{2,i})-I(X_{1,i};Y_{2,i}|X_{2,i})-I(U_i;Y_i|X_{2,i},Y_{2,i}))\\
&\leq \sum_{i=1}^{N}(I(X_{1,i};Y_i|X_{2,i})-I(X_{1,i};Y_{2,i}|X_{2,i}))\\
&\overset{(g)}{=} I(X_1;Y|X_2)-I(X_1;Y_2|X_2), \qquad (6)
\end{aligned}
$$

where (c) is from $Y_2^N \rightarrow (X_2^N,Y^N) \rightarrow X_1^N$, (d) is from $Y_2^{i-1} \rightarrow (X_2^N,Y^{i-1}) \rightarrow Y_{2,i}$, (e) is from the definition $U_i \triangleq (Y^{i-1},X_{2,i+1}^N,X_2^{i-1})$, (f) is from $U_i \rightarrow (X_{2,i},Y_i) \rightarrow Y_{2,i}$, and (g) is from the definitions that $X_1 \triangleq (X_{1,J},J)$, $X_2 \triangleq (X_{2,J},J)$, $Y \triangleq Y_J$, $Y_2 \triangleq Y_{2,J}$ where J is a random variable (uniformly distributed over $\{1,2,...,N\}$), and it is independent of $X_{1,i}$, $X_{2,i}$, Y_i and $Y_{2,i}$.

(Proof of $R_{e2} \leq I(X_2;Y|X_1)-I(X_2;Y_1|X_1)$**)** The proof is analogous to the proof of $R_{e1} \leq I(X_1;Y|X_2)-I(X_1;Y_2|X_2)$.

The Markov chain $(X_1, X_2) \rightarrow Y \rightarrow (Y_1, Y_2)$ is directly obtained from the definitions $X_1 \triangleq (X_{1,J}, J)$, $X_2 \triangleq (X_{2,J}, J)$, $Y \triangleq Y_J$, $Y_2 \triangleq Y_{2,J}$ and $Y_1 \triangleq Y_{1,J}$.

The proof of Theorem 2 is completed.

APPENDIX C
PROOF OF THEOREM 3 AND THEOREM 4

A. *Proof of Theorem 3*

The achievability proof follows by computing the mutual information terms in Theorem 1 with the following joint distributions:

$$X_1^{'} \sim \mathcal{N}(0, \alpha P_1) \text{ and } X_2^{'} \sim \mathcal{N}(0, \beta P_2).$$

$$X_1 = \sqrt{\frac{(1-\alpha)P_1}{P_2}} X_2 + X_1^{'} \text{ and } X_2 = \sqrt{\frac{(1-\beta)P_2}{P_1}} X_1 + X_2^{'}.$$

$X_1^{'}$ is independent of $X_2^{'}$.

B. *Proof of Theorem 4*

The proof of $R_{e1} \leq \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0}) - \frac{1}{2}\log(1+\frac{\alpha P_1}{N_0+N_2})$ and $R_{e2} \leq \frac{1}{2}\log(1+\frac{\beta P_2}{N_0}) - \frac{1}{2}\log(1+\frac{\beta P_2}{N_0+N_1})$ can be directly obtained from [13, p. 1000-1001] by letting $R_0 = 0$ and Q be a constant. Other inequalities in Theorem 3 are from the capacity region of the Gaussian MAC, and they are easily obtained from [13, p. 999-1000]. Therefore, the full details are omitted here.

APPENDIX D
PROOF OF THEOREM 5 AND THEOREM 6

The proof of Theorem 5 is along the lines of Appendix A. The proof of Theorem 6 is obtained by computing the mutual information terms in Theorem 2, see the followings.

All the random variables take values in $\{0, 1\}$. Let $Pr\{X_1 = 0\} = \alpha$, $Pr\{X_1 = 1\} = 1-\alpha$, $Pr\{X_2 = 0\} = \beta$ and $Pr\{X_2 = 1\} = 1-\beta$. Note that X_1, X_2, Y, Y_1 and Y_2 satisfy

$$Y = X_1 \cdot X_2, Y_1 = Y \oplus Z_1, Y_2 = Y \oplus Z_2, \tag{7}$$

where X_1 is independent of X_2, and $Pr\{Z_1 = 0\} = 1-p$, $Pr\{Z_1 = 1\} = p$, $Pr\{Z_2 = 0\} = 1-q$, $Pr\{Z_2 = 1\} = q$.

The joint probability $p_{X_1 X_2 Y}$ is calculated by (8).

$$p_{X_1,X_2,Y}(x_1, x_2, y) = p_{Y|X_1,X_2}(y|x_1, x_2) p_{X_1}(x_1) p_{X_2}(x_2). \tag{8}$$

The joint probability $p_{X_1X_2Y_1}$ is calculated by (9).

$$p_{X_1,X_2,Y_1}(x_1,x_2,y_1)=\sum_{y}p_{Y_1|Y}(y_1|y)p_{Y|X_1,X_2}(y|x_1,x_2)p_{X_1}(x_1)p_{X_2}(x_2). \tag{9}$$

The joint probability $p_{X_1X_2Y_2}$ is calculated by (10).

$$p_{X_1,X_2,Y_2}(x_1,x_2,y_2)=\sum_{y}p_{Y_2|Y}(y_2|y)p_{Y|X_1,X_2}(y|x_1,x_2)p_{X_1}(x_1)p_{X_2}(x_2). \tag{10}$$

Then, the mutual information term $I(X_1;Y|X_2)$ is

$$I(X_1;Y|X_2)=(1-\beta)h(\alpha)\leq h(\alpha)\leq 1, \tag{11}$$

where $h(\alpha)=-\alpha\log(\alpha)-(1-\alpha)\log(1-\alpha)$. Similarly, $I(X_2;Y|X_1)\leq h(\beta)\leq 1$, $I(X_1,X_2;Y)=h(\alpha+\beta-\alpha\beta)\leq 1$, $I(X_2;Y|X_1)-I(X_2;Y_1|X_1)\leq h(\beta)+h(p)-h(\beta+p-2\beta p)\leq h(p)$ and $I(X_1;Y|X_2)-I(X_1;Y_2|X_2)\leq h(\alpha)+h(q)-h(\alpha+q-2\alpha p)\leq h(q)$.

Theorem 5 and Theorem 6 are obtained.

APPENDIX E

PROOF OF THE CONVERSE PART OF THEOREM 7

In this section, we establish the converse part of Theorem 7: all the achievable (R_1,R_2,R_e) triples are contained in the set $\mathcal{R}^{(\mathcal{D})}$. We will prove the inequalities in Theorem 7 in the remaining of this section.

(Proof of $0\leq R_1\leq I(V;Y|U_2)$) The proof of this inequality is as follows.

$$\begin{aligned}
\frac{1}{N}H(W_1) &\overset{(a)}{\leq} \frac{1}{N}(H(W_1|W_2)+\delta(P_e)-H(W_1|W_2,Y^N))\\
&= \frac{1}{N}(I(W_1;Y^N|W_2)+\delta(P_e))\\
&= \frac{1}{N}\sum_{i=1}^{N}(H(Y_i|Y^{i-1},W_2)-H(Y_i|Y^{i-1},W_2,W_1))+\frac{\delta(P_e)}{N}\\
&\leq \frac{1}{N}\sum_{i=1}^{N}(H(Y_i|Y^{i-1},W_2)-H(Y_i|Y^{i-1},W_2,W_1,Z_{i+1}^N))+\frac{\delta(P_e)}{N}\\
&\overset{(b)}{=} \frac{1}{N}\sum_{i=1}^{N}(H(Y_i|U_{2,i})-H(Y_i|U_{2,i},V_i))+\frac{\delta(P_e)}{N}\\
&\overset{(c)}{=} I(V;Y|U_2)+\frac{\delta(P_e)}{N},
\end{aligned} \tag{12}$$

where (a) is from the Fano's inequality and the fact that W_1 is independent of W_2, (b) is from the definitions $U_{2,i}\triangleq(Y^{i-1},W_2)$ and $V_i\triangleq(Y^{i-1},W_2,W_1,Z_{i+1}^N)$, and (c) is from the definitions that $U_2\triangleq(U_{2,J},J)$, $V\triangleq(V_J,J)$, $Y\triangleq Y_J$, where J is a random variable (uniformly distributed over $\{1,2,...,N\}$), and it is independent of $U_{2,i}$, V_i and Y_i.

By using $P_e\leq\epsilon$, $R_1=\lim_{N\rightarrow\infty}\frac{H(W_1)}{N}$ and (12), it is easy to see that $0\leq R_1\leq I(V;Y|U_2)$.

(Proof of $0\leq R_2\leq I(V;Y|U_1)$) The proof is similar to the proof of $0\leq R_1\leq I(V;Y|U_2)$, and it is omitted here. Note that $U_1\triangleq(Y^{J-1},W_1,J)$.

(Proof of $0 \leq R_1 + R_2 \leq I(V;Y)$**)**

$$\begin{aligned}
\frac{1}{N}H(W_1, W_2) &\overset{(1)}{\leq} \frac{1}{N}(I(W_1, W_2; Y^N) + \delta(P_e)) \\
&= \frac{1}{N}\sum_{i=1}^{N}(H(Y_i|Y^{i-1}) - H(Y_i|Y^{i-1}, W_1, W_2)) + \frac{\delta(P_e)}{N} \\
&\leq \frac{1}{N}\sum_{i=1}^{N}(H(Y_i) - H(Y_i|Y^{i-1}, W_1, W_2, Z_{i+1}^N)) + \frac{\delta(P_e)}{N} \\
&\overset{(2)}{=} \frac{1}{N}\sum_{i=1}^{N}(H(Y_i) - H(Y_i|V_i)) + \frac{\delta(P_e)}{N} \\
&\overset{(3)}{=} I(V;Y) + \frac{\delta(P_e)}{N}, \qquad (13)
\end{aligned}$$

where (1) is from the Fano's inequality, (2) is from the definition $V_i \triangleq (Y^{i-1}, W_2, W_1, Z_{i+1}^N)$, and (3) is from the definitions that $V \triangleq (V_J, J)$, $Y \triangleq Y_J$, where J is a random variable (uniformly distributed over $\{1, 2, ..., N\}$), and it is independent of V_i and Y_i.

By using $P_e \leq \epsilon$, $R_1 = \lim_{N\to\infty} \frac{H(W_1)}{N}$, $R_2 = \lim_{N\to\infty} \frac{H(W_2)}{N}$ and (13), it is easy to see that $0 \leq R_1 + R_2 \leq I(V;Y)$.

(Proof of $0 \leq R_e \leq R_1 + R_2$**)** This inequality is obtained by the following (14).

$$R_e \leq \lim_{N\to\infty} \frac{1}{N}H(W_1, W_2|Y^N) \leq \lim_{N\to\infty} \frac{1}{N}H(W_1, W_2) = R_1 + R_2. \qquad (14)$$

(Proof of $R_e \leq I(V;Y|U) - I(V;Z|U)$**)** The proof is obtained by substituting (16), (17), (18) and (21) into (15), and using $P_e \leq \epsilon$ and the definitions $U \triangleq (Y^{J-1}; Z_{J+1}^N, J)$ and $V \triangleq (W_1, W_2, Y^{J-1}; Z_{J+1}^N, J)$.

$$\begin{aligned}
R_e &\leq \lim_{N\to\infty} \frac{1}{N}H(W_1, W_2|Z^N) \\
&= \lim_{N\to\infty} \frac{1}{N}(H(W_1, W_2) - I(W_1, W_2; Z^N)) \\
&= \lim_{N\to\infty} \frac{1}{N}(I(W_1, W_2; Y^N) + H(W_1, W_2|Y^N) - I(W_1, W_2; Z^N)) \\
&\overset{(a)}{\leq} \lim_{N\to\infty} \frac{1}{N}(I(W_1, W_2; Y^N) - I(W_1, W_2; Z^N) + \delta(P_e)), \qquad (15)
\end{aligned}$$

where (a) is from the Fano's inequality.

$$\begin{aligned}
I(W_1, W_2; Y^N) &= \sum_{i=1}^{N}(H(Y_i|Y^{i-1}) - H(Y_i|Y^{i-1}, W_1, W_2)) \\
&= \sum_{i=1}^{N}(H(Y_i|Y^{i-1}) - H(Y_i|Y^{i-1}, W_1, W_2) - H(Y_i|Y^{i-1}, Z_{i+1}^N) + H(Y_i|Y^{i-1}, Z_{i+1}^N) \\
&\quad - H(Y_i|Y^{i-1}, W_1, W_2, Z_{i+1}^N) + H(Y_i|Y^{i-1}, W_1, W_2, Z_{i+1}^N)) \\
&= \sum_{i=1}^{N}(I(Y_i; Z_{i+1}^N|Y^{i-1}) - I(Y_i; Z_{i+1}^N|Y^{i-1}, W_1, W_2) + I(Y_i; W_1, W_2|Y^{i-1}, Z_{i+1}^N)). \qquad (16)
\end{aligned}$$

$$\begin{aligned} I(W_1,W_2;Z^N) &= \sum_{i=1}^{N}(H(Z_i|Z_{i+1}^N)-H(Z_i|Z_{i+1}^N,W_1,W_2)) \\ &= \sum_{i=1}^{N}(H(Z_i|Z_{i+1}^N)-H(Z_i|Z_{i+1}^N,W_1,W_2)-H(Z_i|Y^{i-1},Z_{i+1}^N)+H(Z_i|Y^{i-1},Z_{i+1}^N) \\ &\quad -H(Z_i|Y^{i-1},W_1,W_2,Z_{i+1}^N)+H(Z_i|Y^{i-1},W_1,W_2,Z_{i+1}^N)) \\ &= \sum_{i=1}^{N}(I(Z_i;Y^{i-1}|Z_{i+1}^N)-I(Z_i;Y^{i-1}|Z_{i+1}^N,W_1,W_2)+I(Z_i;W_1,W_2|Y^{i-1},Z_{i+1}^N)). \quad (17) \end{aligned}$$

Note that

$$\sum_{i=1}^{N} I(Z_i;Y^{i-1}|Z_{i+1}^N)=\sum_{i=1}^{N} I(Y_i;Z_{i+1}^N|Y^{i-1}). \quad (18)$$

Proof of (18): The right hand side of (18) is equal to

$$\sum_{i=1}^{N} I(Y_i;Z_{i+1}^N|Y^{i-1})=\sum_{i=1}^{N}\sum_{j=i+1}^{N} I(Y_i;Z_j|Y^{i-1},Z_{j+1}^N), \quad (19)$$

and the left hand side of (18) is equal to

$$\begin{aligned} \sum_{i=1}^{N} I(Z_i;Y^{i-1}|Z_{i+1}^N) &= \sum_{i=1}^{N}\sum_{j=1}^{i-1} I(Z_i;Y_j|Z_{i+1}^N,Y^{j-1}) \\ &= \sum_{j=1}^{N}\sum_{i=1}^{j-1} I(Z_j;Y_i|Z_{j+1}^N,Y^{i-1}) \\ &= \sum_{i=1}^{N}\sum_{j=i+1}^{N} I(Z_j;Y_i|Z_{j+1}^N,Y^{i-1}), \quad (20) \end{aligned}$$

and therefore, the formula (18) is verified by (19) and (20). ■

Analogously,

$$\sum_{i=1}^{N} I(Y_i;Z_{i+1}^N|Y^{i-1},W_1,W_2)=\sum_{i=1}^{N} I(Z_i;Y^{i-1}|Z_{i+1}^N,W_1,W_2). \quad (21)$$

The Markov chain $(U,U_1,U_2)\rightarrow V\rightarrow (X_1,X_2)\rightarrow (Y,Z)$ is directly obtained from the above definitions.

The proof of the converse part of Theorem 7 is completed.

APPENDIX F

PROOF OF THE DIRECT PART OF THEOREM 7

In this section we establish the direct part of Theorem 7(about existence). Suppose $(R_1,R_2,R_e)\in\mathcal{R}^{\mathcal{D}}$, we will show that (R_1,R_2,R_e) is achievable.

The existence of the encoder-decoder is under the sufficient condition $R_e=I(V;Y|U)-I(V;Z|U)$. Given a triple (R_1,R_2,R_e), choose a joint probability mass function $p_{U,U_1,U_2,V,X_1,X_2,Y,Z}(u,u_1,u_2,v,x_1,x_2,y,z)$ such that

$$0\leq R_1\leq I(V;Y|U_2), 0\leq R_2\leq I(V;Y|U_1), R_1+R_2\leq I(V;Y),$$

$$R_e\leq R_1+R_2, \quad R_e=I(V;Y|U)-I(V;Z|U).$$

The message sets $\mathcal{W}_1$ and $\mathcal{W}_2$ satisfy the following conditions:

$$\lim_{N\to\infty}\frac{1}{N}\log\parallel\mathcal{W}_1\parallel=R_1, \tag{22}$$

$$\lim_{N\to\infty}\frac{1}{N}\log\parallel\mathcal{W}_2\parallel=R_2. \tag{23}$$

Note that

$$\lim_{N\to\infty}\frac{1}{N}\log\parallel\mathcal{W}_1\times\mathcal{W}_2\parallel=R_1+R_2\geq I(V;Y|U)-I(V;Z|U). \tag{24}$$

Now the remaining of this section is organized as follows. The encoding-decoding scheme is introduced in Subsection F-A. For any given $\epsilon>0$, the proofs of $\lim_{N\to\infty}\frac{\log\|\mathcal{W}_1\|}{N}=R_1$, $\lim_{N\to\infty}\frac{\log\|\mathcal{W}_2\|}{N}=R_2$, $\lim_{N\to\infty}\Delta\geq R_e$ and $P_e\leq\epsilon$ are given in Subsection F-B.

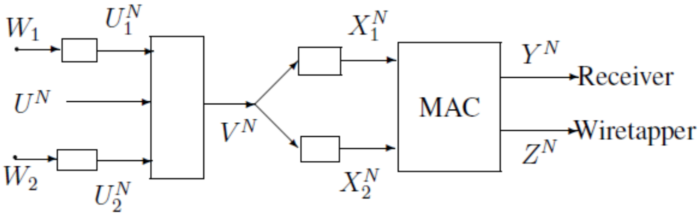

Fig. 10: Code construction for MAC-WT with cooperative encoders

A. *Encoding-decoding Scheme*

The encoding scheme for the MAC-WT with cooperative encoders is in Figure 10. In the reminder of this subsection, we will introduce the realization of the random vectors in Figure 10.

- (**A realization of** U_1^N **and** U_2^N) For each w_1 ($w_1\in\{1,2,...,2^{NR_1}\}$), generate a corresponding codeword $u_1^N(w_1)$ i.i.d. according to the probability mass function $p_{U_1}(u_1)$. Similarly, for each w_2 ($w_1\in\{1,2,...,2^{NR_2}\}$), generate a corresponding codeword $u_2^N(w_2)$ i.i.d. according to the probability mass function $p_{U_2}(u_2)$. $u_1^N(w_1)$ and $u_2^N(w_2)$ are realizations of the random vectors U_1^N and U_2^N, respectively.
- (**A realization of** U^N) Let $u^N(m)$ ($1\leq m\leq 2^{N\gamma}$) be chosen from the strong typical set $T_U^N(\eta^*)$, where η^* is an arbitrary small positive real number and $0\leq\gamma\leq\min\{I(U;Y),I(U;Z)\}$. Moreover, let Φ be a set defined as $\Phi=\{u^N(m):1\leq m\leq 2^{N\gamma}\}$. Note that the elements of Φ are distinguishable. Choose a sequence $u^N(m)$ from the set Φ as a realization of U^N, and label the sequence $u^N(m)$ as m.
- (Step ii) (**A realization of** V^N)

  Let J, L and M be the random variables used for indexing the random vector V^N, and the three random variables take values in the index sets $\mathcal{J}$, $\mathcal{L}$ and $\mathcal{M}$, respectively. Let v_{jlm}^N be a realization of the random vector V^N, where j, l, m run over the index sets $\mathcal{J}$, $\mathcal{L}$ and $\mathcal{M}$. The construction of the sequence v_{jlm}^N is considered in three parts. The first part is about the determination of the size of the indices j, l and m appeared in the sequence v^N_{jlm}. The second part is the full details of how to choose the indices of the sequence v^N_{jlm}. The third part is the construction of the sequence v^N_{jlm}, see the following.

- **(The size of $\mathcal{J}$, $\mathcal{L}$ and $\mathcal{M}$)**

  The indices j, l and m appeared in the sequence v^N_{jlm} respectively run over the index sets $\mathcal{J}$, $\mathcal{L}$, $\mathcal{M}$ with the following properties:

$$\lim_{N\rightarrow\infty}\frac{1}{N}\log\parallel\mathcal{J}\parallel = I(V;Z|U), \tag{25}$$

$$\lim_{N\rightarrow\infty}\frac{1}{N}\log\parallel\mathcal{L}\parallel = I(V;Y|U)-I(V;Z|U), \tag{26}$$

$$\lim_{N\rightarrow\infty}\frac{1}{N}\log\parallel\mathcal{M}\parallel = \gamma, \tag{27}$$

  where γ satisfies $0\leq\gamma\leq\min\{I(U;Y),I(U;Z)\}$.

- **(The chosen of j, l and m)**

  - (Case 1) If $R_1+R_2\geq I(V;Y|U)$, let $\mathcal{W}_1\times\mathcal{W}_2=\mathcal{J}\times\mathcal{L}\times\mathcal{M}$. Therefore, in this case, the chosen of $u^N(m)$ is based on w_1 and w_2.

    The indices j, l and m are chosen based on w_1 and w_2.

  - (Case 2) If $R_1+R_2\leq I(V;Y|U)$, let $\mathcal{W}_1\times\mathcal{W}_2=\mathcal{L}\times\mathcal{K}$, where $\mathcal{K}$ is an arbitrary set such that (24) holds. Let $\bar{g}$ be a mapping of $\mathcal{J}$ into $\mathcal{K}$, partitioning $\mathcal{J}$ into subsets of nearly equal size. Note that in this case, the chosen of $u^N(m)$ is not based on w_1 and w_2.

    The index j is randomly chosen from the set $\bar{g}^{-1}(k)\subset\mathcal{J}$ (where $\bar{g}^{-1}$ is the inverse mapping of $\bar{g}$, and $k\in\mathcal{K}$).

    The index m is chosen according to the label of $u^N(m)$.

    The index l is chosen from $\mathcal{L}$.

- **(The construction of v^N_{jlm})** The construction of v^N_{jlm} is as follows. For each $m\in\mathcal{M}$, there exists a U-typical sequence $u^N(m)\in\Phi$ such that all the v^N_{jlm} are $V|U$-generated by $u^N(m)$, and this indicates that $v^N_{jlm}\in T^N_V(\eta^{**})$, where η^{**} is an arbitrary small positive real number.

- **(A realization of X^N_1 and X^N_2)** x^N_1 is generated according to a new discrete memoryless channel (DMC) with input v^N_{jlm} and output x^N_1. The transition probability of this new DMC is $p_{X_1|V}(x_1|v)$.

  Similarly, x^N_2 is generated according to a new discrete memoryless channel (DMC) with input v^N_{jlm} and output x^N_2. The transition probability of this new DMC is $p_{X_2|V}(x_2|v)$.

- **(Decoding scheme of the legitimate receiver)** For given y^N, try to find a sequence $v^N_{\hat{j}\hat{l}\hat{m}}$ such that $(v^N_{\hat{j}\hat{l}\hat{m}},y^N)\in T^N_{VY}(\epsilon^{***})$. If there exist sequences with the same indices $\hat{j}$, $\hat{l}$ and $\hat{m}$, put out the corresponding $\hat{w}_1$ and $\hat{w}_2$, else declare a decoding error.

B. Achievability Proof

By using the above definitions, it is easy to verify that $\lim_{N\rightarrow\infty}\frac{\log\|\mathcal{W}_1\|}{N}=R_1$ and $\lim_{N\rightarrow\infty}\frac{\log\|\mathcal{W}_2\|}{N}=R_2$.

Then, observing the construction of V^N, it is easy to see that the codewords of V^N are upper-bounded by $2^{NI(V;Y)}$. Therefore, from the standard channel coding theorem, for any given $\epsilon > 0$ and sufficiently large N, we have $P_e \leq \epsilon$.

It remains to show that $\lim_{N\to\infty} \Delta \geq R_e$, see the following. Let M be the random variable defined as the third coordinate of the actual value of V^N. Then

$$\begin{aligned}
\lim_{N\to\infty} \Delta &\triangleq \lim_{N\to\infty} \frac{1}{N} H(W_1, W_2|Z^N) \\
&\geq \lim_{N\to\infty} \frac{1}{N} H(W_1, W_2|Z^N, M) \\
&= \lim_{N\to\infty} \frac{1}{N} (H(W_1, W_2, Z^N|M) - H(Z^N|M)) \\
&= \lim_{N\to\infty} \frac{1}{N} (H(W_1, W_2, V^N, Z^N|M) - H(V^N|W_1, W_2, Z^N, M) - H(Z^N|M)) \\
&\overset{(a)}{=} \lim_{N\to\infty} \frac{1}{N} (H(W_1, W_2, V^N|M) + H(Z^N|V^N) - H(V^N|W_1, W_2, Z^N, M) - H(Z^N|M)) \\
&\geq \lim_{N\to\infty} \frac{1}{N} (H(V^N|M) + H(Z^N|V^N) - H(V^N|W_1, W_2, Z^N, M) - H(Z^N|M)), \qquad (28)
\end{aligned}$$

where (a) is from the Markov chain $(W_1, W_2, M) \to V^N \to Z^N$.

The first term in (28) can be bounded as follows.

$$\lim_{N\to\infty} \frac{1}{N} H(V^N|M) \geq I(V; Y|U), \tag{29}$$

where (29) is from the property of the strong typical sequences and the construction of V^N, see [2, p. 343].

The second term in (28) is as follows.

$$\lim_{N\to\infty} \frac{1}{N} H(Z^N|V^N) \geq H(Z|V), \tag{30}$$

where (30) is from a similar proof in [2, p. 343].

For the third term in (28), we have

$$\lim_{N\to\infty} \frac{1}{N} H(V^N|W_1, W_2, Z^N, M) = 0. \tag{31}$$

This is because for given m, w_1 and w_2, there are at most $2^{NI(V;Z|U)}$ codewords left for v^N. Then note that

$$\begin{aligned}
I(V; Z|U) &= H(Z|U) - H(Z|V) \\
&\leq I(V; Z).
\end{aligned}$$

From the standard channel coding theorem and the Fano's inequality, we have (31).

For the fourth term in (28), we have

$$\lim_{N\to\infty} \frac{1}{N} H(Z^N|M) \leq H(Z|U), \tag{32}$$

and this is from a standard technique as in [2, p. 343].

Substituting (29), (30), (31) and (32) into (28), we have

$$\lim_{N\to\infty} \Delta \geq I(V; Y|U) - I(V; Z|U). \tag{33}$$

Therefore, the achievability proof for Theorem 7 is completed.

APPENDIX G

SIZE CONSTRAINTS OF THE AUXILIARY RANDOM VARIABLES IN THEOREM 7

By using the support lemma (see [17], p.310), it suffices to show that the random variables U_1, U_2, U and V can be replaced by new ones, preserving the Markovity $(U, U_1, U_2) \rightarrow V \rightarrow (X_1, X_2) \rightarrow (Y, Z)$ and the mutual information $I(V; Y|U_1)$, $I(V; Y|U_2)$, $I(V; Y)$, $I(V; Y|U)$, $I(V; Z|U)$, and furthermore, the ranges of the new U_1, U_2, U and V satisfy:

$$\|\mathcal{U}\| \leq \|\mathcal{X}_1\|\|\mathcal{X}_2\| + 1,$$

$$\|\mathcal{U}_1\| \leq \|\mathcal{X}_1\|\|\mathcal{X}_2\|,$$

$$\|\mathcal{U}_2\| \leq \|\mathcal{X}_1\|\|\mathcal{X}_2\|,$$

$$\|\mathcal{V}\| \leq (\|\mathcal{X}_1\|\|\mathcal{X}_2\| + 1)^2\|\mathcal{X}_1\|^2\|\mathcal{X}_2\|^2.$$

The proof is in the reminder of this section.

Let

$$\bar{p} = p_{X_1X_2}(x_1, x_2). \tag{34}$$

Define the following continuous scalar functions of $\bar{p}$:

$$f_{X_1X_2}(\bar{p}) = p_{X_1X_2}(x_1, x_2), \quad f_Y(\bar{p}) = H(Y), \quad f_Z(\bar{p}) = H(Z).$$

Since there are $\|\mathcal{X}_1\|\|\mathcal{X}_2\| - 1$ functions of $f_{X_1X_2}(\bar{p})$, the total number of the continuous scalar functions of $\bar{p}$ is $\|\mathcal{X}_1\|\|\mathcal{X}_2\|$+1.

Let $\bar{p}_{X_1X_2|U} = Pr\{X_1 = x_1, X_2 = x_2|U = u\}$. With these distributions $\bar{p}_{X_1X_2|U}$, we have

$$p_{X_1X_2}(x_1, x_2) = \sum_{u\in\mathcal{U}} p(U = u) f_{X_1X_2}(\bar{p}_{X_1X_2|U}), \tag{35}$$

$$H(Y|U) = \sum_{u\in\mathcal{U}} p(U = u) f_Y(\bar{p}_{X_1X_2|U}), \tag{36}$$

$$H(Z|U) = \sum_{u\in\mathcal{U}} p(U = u) f_Z(\bar{p}_{X_1X_2|U}). \tag{37}$$

According to the support lemma ([17], p.310), the random variable U can be replaced by new ones such that the new U takes at most $\|\mathcal{X}_1\|\|\mathcal{X}_2\| + 1$ different values and the expressions (35), (36) and (37) are preserved.

Similarly, we can prove that $\|\mathcal{U}_1\| \leq \|\mathcal{X}_1\|\|\mathcal{X}_2\|$ and $\|\mathcal{U}_2\| \leq \|\mathcal{X}_1\|\|\mathcal{X}_2\|$.

Once the alphabets of U, U_1, U_2 are fixed, we apply similar arguments to bound the alphabet of V, see the following. Define $\|\mathcal{X}_1\|\|\mathcal{X}_2\| + 1$ continuous scalar functions of $\bar{p}_{X_1X_2}$:

$$f_{X_1X_2}(\bar{p}_{X_1X_2}) = p_{X_1X_2}(x_1, x_2), f_Y(\bar{p}_{X_1X_2}) = H(Y), f_Z(\bar{p}_{X_1X_2}) = H(Z),$$

where of the functions $f_{X_1X_2}(\bar{p}_{X_1X_2})$, only $\|\mathcal{X}_1\|\|\mathcal{X}_2\| - 1$ are to be considered.

For fixed u, u_1 and u_2, let $\bar{p}_{X_1X_2|V} = Pr\{X_1 = x_1, X_2 = x_2|V = v\}$. With these distributions $\bar{p}_{X_1X_2|V}$, we have

$$Pr\{X_1 = x_1, X_2 = x_2|U = u, U_1 = u_1, U_2 = u_2\} = \sum_{v\in\mathcal{V}} Pr\{V = v|U = u, U_1 = u_1, U_2 = u_2\} f_{X_1X_2}(\bar{p}_{X_1X_2|V}), \tag{38}$$

$$H(Y|V) = \sum_{v\in\mathcal{V}} f_Y(\bar{p}_{X_1X_2|V}) Pr\{V = v|U = u, U_1 = u_1, U_2 = u_2\}, \tag{39}$$

$$H(Z|V) = \sum_{v\in\mathcal{V}} f_Z(\bar{p}_{X_1X_2|V}) Pr\{V = v|U = u, U_1 = u_1, U_2 = u_2\}. \tag{40}$$

By the support lemma ([17], p.310), for fixed u, u_1 and u_2, the size of the alphabet of the random variable V can not be larger than $\|\mathcal{X}_1\|\|\mathcal{X}_2\| + 1$, and therefore, $\|\mathcal{V}\| \leq (\|\mathcal{X}_1\|\|\mathcal{X}_2\| + 1)^2\|\mathcal{X}_1\|^2\|\mathcal{X}_2\|^2$ is proved.

APPENDIX H

PROOF OF THEOREM 8

The only difference between Theorem 7 and Theorem 8 is the upper bound of R_e. Since the degraded MAC-WT with cooperative encoders is a special case of the general model, and therefore, the converse proof of Theorem 8 can be directly obtained from the converse proof of Theorem 7 and (4.3). Now it remains to prove the achievability, see the remainder of this section.

The encoding-decoding scheme for Theorem 8 is a special case of that for Theorem 7, see Figure 11.

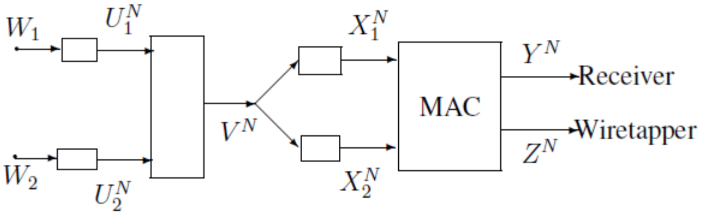

Fig. 11: Code construction for degraded MAC-WT with cooperative encoders

The existence of the encoder-decoder is under the sufficient condition $R_e = I(V;Y) - I(V;Z)$. Given a triple (R_1, R_2, R_e), choose a joint probability mass function $p_{U_1,U_2,V,X_1,X_2,Y,Z}(u_1, u_2, v, x_1, x_2, y, z)$ such that

$$0 \leq R_1 \leq I(V;Y|U_2), 0 \leq R_2 \leq I(V;Y|U_1), R_1 + R_2 \leq I(V;Y),$$

$$R_e \leq R_1 + R_2, R_e = I(V;Y) - I(V;Z).$$

The message sets $\mathcal{W}_1$ and $\mathcal{W}_2$ satisfy the following conditions:

$$\lim_{N\to\infty} \frac{1}{N} \log \parallel \mathcal{W}_1 \parallel = R_1, \tag{41}$$

$$\lim_{N\to\infty} \frac{1}{N} \log \parallel \mathcal{W}_2 \parallel = R_2. \tag{42}$$

Note that

$$\lim_{N\to\infty}\frac{1}{N}\log\parallel\mathcal{W}_1\times\mathcal{W}_2\parallel=R_1+R_2\geq I(V;Y)-I(V;Z). \tag{43}$$

The construction of U_1^N and U_2^N in Figure 11 is the same as those in Appendix G, and V^N is constructed as follows.

Generate $2^{N(I(V;Y)-\epsilon_N)}$ codewords v^N ($\epsilon_N\to\infty$ as $N\to\infty$), and each of them is uniformly drawn from the strong typical set $T_V^N(\eta)$. Divide the $2^{N(I(V;Y)-\epsilon_N)}$ codewords into $2^{N(R_1+R_2)}$ bins, and each bin corresponds to a specific value in $\mathcal{W}_1\times\mathcal{W}_2$.

(**A realization of** X_1^N **and** X_2^N) x_1^N is generated according to a new discrete memoryless channel (DMC) with input v_{jlm}^N and output x_1^N. The transition probability of this new DMC is $p_{X_1|V}(x_1|v)$.

Similarly, x_2^N is generated according to a new discrete memoryless channel (DMC) with input v_{jlm}^N and output x_2^N. The transition probability of this new DMC is $p_{X_2|V}(x_2|v)$.

(**Decoding scheme of the legitimate receiver**) For given y^N, try to find a sequence $v^N(\hat{w}_1,\hat{w}_2)$ such that $(v^N(\hat{w}_1,\hat{w}_2),y^N)\in T_{VY}^N(\epsilon^{***})$. If there exist sequences with the same $\hat{w}_1$ and $\hat{w}_2$, put out the corresponding $\hat{w}_1$ and $\hat{w}_2$, else declare a decoding error.

By using the above definitions, it is easy to verify that $\lim_{N\to\infty}\frac{\log\|\mathcal{W}_1\|}{N}=R_1$ and $\lim_{N\to\infty}\frac{\log\|\mathcal{W}_2\|}{N}=R_2$.

Then, observing the construction of V^N, it is easy to see that the codewords of V^N are upper-bounded by $2^{NI(V;Y)}$. Therefore, from the standard channel coding theorem, for any given $\epsilon>0$ and sufficiently large N, we have $P_e\leq\epsilon$.

It remains to show that $\lim_{N\to\infty}\Delta\geq R_e$, see the following.

$$\begin{aligned}
\lim_{N\to\infty}\Delta &\triangleq \lim_{N\to\infty}\frac{1}{N}H(W_1,W_2|Z^N)\\
&= \lim_{N\to\infty}\frac{1}{N}(H(W_1,W_2,Z^N)-H(Z^N))\\
&= \lim_{N\to\infty}\frac{1}{N}(H(W_1,W_2,V^N,Z^N)-H(V^N|W_1,W_2,Z^N)-H(Z^N))\\
&= \lim_{N\to\infty}\frac{1}{N}(H(V^N|W_1,W_2)+H(W_1,W_2)-H(V^N|W_1,W_2,Z^N)-I(V^N;Z^N)). \qquad (44)
\end{aligned}$$

The first term in (44) is

$$\lim_{N\to\infty}\frac{1}{N}H(V^N|W_1,W_2)=I(V;Y)-R_1-R_2. \tag{45}$$

The second term in (44) is as follows.

$$\lim_{N\to\infty}\frac{1}{N}H(W_1,W_2)=R_1+R_2. \tag{46}$$

For the third term in (44), we have

$$\lim_{N\to\infty}\frac{1}{N}H(V^N|W_1,W_2,Z^N)=0. \tag{47}$$

This is because for given w_1 and w_2, there are $2^{N(I(V;Y)-\epsilon_N-R_1-R_2)}$ codewords left for v^N. Then note that

$$\begin{aligned}
I(V;Y)-\epsilon_N-R_2-R_1 &\leq I(V;Y)-\epsilon_N-R_e \\
&= I(V;Y)-\epsilon_N-(I(V;Y)-I(V;Z)) \\
&= I(V;Z)-\epsilon_N,
\end{aligned}$$

and $\epsilon_N \to 0$ as $N \to \infty$. From the standard channel coding theorem and the Fano's inequality, we have (47).

For the fourth term in (44), we have

$$\lim_{N\to\infty}\frac{1}{N}I(V^N;Z^N) \leq I(V;Z), \tag{48}$$

and this is from a standard technique as in [2, p. 343].

Substituting (45), (46), (47) and (48) into (44), we have

$$\lim_{N\to\infty}\Delta \geq I(V;Y)-I(V;Z)=R_e. \tag{49}$$

$\lim_{N\to\infty}\Delta \geq R_e$ is proved. Therefore, the achievability proof for Theorem 8 is completed.

APPENDIX I

PROOF OF THEOREM 9

Suppose $(R_1,R_2,R_e)\in\mathcal{R}^{\mathcal{G}}$, we will show that (R_1,R_2,R_e) is achievable. Since $\mathcal{R}^{\mathcal{G}}=\mathcal{L}^{(1)}\cup\mathcal{L}^{(2)}\cup\mathcal{L}^{(3)}\cup\mathcal{L}^{(4)}$, we need to prove that $(R_1,R_2,R_e)\in\mathcal{L}^{(i)}$ $(i=1,2,3,4)$ is achievable.

Note that $\mathcal{L}^{(1)}$ is analogous to $\mathcal{L}^{(2)}$, and $\mathcal{L}^{(3)}$ is analogous to $\mathcal{L}^{(4)}$. Thus, in the remainder of this section, we only prove that $(R_1,R_2,R_e)\in\mathcal{L}^{(1)}$ and $(R_1,R_2,R_e)\in\mathcal{L}^{(3)}$ are achievable.

A. Achievability of $\mathcal{L}^{(1)}$

The existence of the encoder-decoder is under the sufficient conditions that $R_e=I(X_2;Y|X_1)-I(X_2;Z|X_1)+R_1$. Given a triple (R_1,R_2,R_e), choose a joint probability mass function $p_{X_1,X_2,Y,Z}(x_1,x_2,y,z)$ such that

$$0\leq R_1\leq I(X_1;Y)-I(X_1;Z), 0\leq R_2\leq I(X_2;Y|X_1), R_1+R_2\leq I(X_1,X_2;Y),$$

$$R_e\leq R_1+R_2, R_e=I(X_2;Y|X_1)-I(X_2;Z|X_1)+R_1.$$

Note that $R_e=I(X_2;Y|X_1)-I(X_2;Z|X_1)+R_1$ implies that

$$R_2\geq I(X_2;Y|X_1)-I(X_2;Z|X_1). \tag{50}$$

Define

$$R_1=I(X_1;Y)-I(X_1;Z)-\gamma, \tag{51}$$

where $\gamma\geq 0$.

The confidential message sets $\mathcal{W}_1$ and $\mathcal{W}_2$ satisfy the following conditions:

$$\lim_{N\to\infty}\frac{1}{N}\log\parallel\mathcal{W}_1\parallel=R_1, \lim_{N\to\infty}\frac{1}{N}\log\parallel\mathcal{W}_2\parallel=R_2. \tag{52}$$

Code-book generation: Generate $2^{N(I(X_1;Y)-\gamma-\epsilon_N)}$ codewords x_1^N ($\epsilon_N \to \infty$ as $N \to \infty$), and each of them is uniformly drawn from the strong typical set $T_{X_1}^N(\eta)$. Divide the $2^{N(I(X_1;Y)-\gamma-\epsilon_N)}$ codewords into 2^{NR_1} bins, and each bin corresponds to a specific value in $\mathcal{W}_1$.

Analogously, generate $2^{N(I(X_2;Y|X_1)-\epsilon_N)}$ codewords x_2^N, and each of them is uniformly drawn from the strong typical set $T_{X_2}^N(\eta)$. Divide the $2^{N(I(X_2;Y|X_1)-\epsilon_N)}$ codewords into 2^{NR_2} bins, and each bin corresponds to a specific value in $\mathcal{W}_2$.

Decoding scheme: For a given y^N, try to find a pair of sequences $(x_1^N(\hat{w}_1), x_2^N(\hat{w}_2))$ such that $(x_1^N(\hat{w}_1), x_2^N(\hat{w}_2), y^N) \in T_{X_1X_2Y}^N(\epsilon)$. If there exist sequences with the same indices $\hat{w}_1$ and $\hat{w}_2$, put out the corresponding $\hat{w}_1$ and $\hat{w}_2$, else declare a decoding error.

Proof of the achievability: By using the above definitions, it is easy to verify that $\lim_{N\to\infty} \frac{\log\|\mathcal{W}_1\|}{N} = R_1$ and $\lim_{N\to\infty} \frac{\log\|\mathcal{W}_2\|}{N} = R_2$.

Then, note that the codewords of x_1^N and x_2^N are respectively upper bounded by $2^{NI(X_1;Y)}$ and $2^{NI(X_2;Y|X_1)}$. Therefore, from the standard techniques as in [18, Ch. 14], we have $P_e \le \epsilon$.

It remains to show that $\lim_{N\to\infty} \Delta \ge R_e$, see the following.

$$\begin{aligned}
\lim_{N\to\infty} \Delta &\triangleq \lim_{N\to\infty} \frac{1}{N} H(W_1, W_2|Z^N) \\
&= \lim_{N\to\infty} \frac{1}{N}(H(W_1|Z^N) + H(W_2|Z^N, W_1)) \\
&\ge \lim_{N\to\infty} \frac{1}{N}(H(W_1|Z^N) + H(W_2|Z^N, W_1, X_1^N)) \\
&\overset{(a)}{=} \lim_{N\to\infty} \frac{1}{N}(H(W_1|Z^N) + H(W_2|Z^N, X_1^N)) \\
&= \lim_{N\to\infty} \frac{1}{N}(H(W_1, Z^N) - H(Z^N) + H(W_2, Z^N, X_1^N) - H(Z^N, X_1^N)) \\
&= \lim_{N\to\infty} \frac{1}{N}(H(W_1, Z^N, X_1^N) - H(X_1^N|W_1, Z^N) - H(Z^N) \\
&\quad +H(W_2, Z^N, X_1^N, X_2^N) - H(X_2^N|W_2, Z^N, X_1^N) - H(Z^N, X_1^N)) \\
&\overset{(b)}{=} \lim_{N\to\infty} \frac{1}{N}(H(Z^N|X_1^N) + H(W_1) + H(X_1^N|W_1) - H(X_1^N|W_1, Z^N) - H(Z^N) \\
&\quad +H(Z^N|X_1^N, X_2^N) + H(X_1^N) + H(W_2) + H(X_2^N|W_2) - H(X_2^N|W_2, Z^N, X_1^N) - H(Z^N, X_1^N)) \\
&= \lim_{N\to\infty} \frac{1}{N}(H(W_1) + H(X_1^N|W_1) - H(X_1^N|W_1, Z^N) + H(X_2^N|W_2) + H(W_2) \\
&\quad -H(X_2^N|W_2, Z^N, X_1^N) - I(X_1^N, X_2^N; Z^N)),
\end{aligned} \tag{53}$$

where (a) is from $W_1 \to (X_1^N, Z^N) \to W_2$, and (b) is from $W_1 \to X_1^N \to Z^N$ and $W_2 \to (X_1^N, X_2^N) \to Z^N$.

The first term in (53) is

$$\lim_{N\to\infty} \frac{1}{N} H(W_1) = R_1. \tag{54}$$

The second term in (53) can be bounded as follows.

$$\lim_{N\to\infty} \frac{1}{N} H(X_1^N|W_1) = I(X_1;Y) - \gamma - R_1. \tag{55}$$

For the third term in (53), we have

$$\lim_{N\to\infty}\frac{1}{N}H(X_1^N|W_1,Z^N)=0. \tag{56}$$

This is because for a given w_1, there are $2^{N(I(X_1;Y)-\gamma-\epsilon_N-R_1)}$ codewords left for x_1^N. Then note that

$$\begin{aligned} I(X_1;Y)-\gamma-\epsilon_N-R_1 &= I(X_1;Y)-\gamma-\epsilon_N-(I(X_1;Y)-I(X_1;Z)-\gamma) \\ &= I(X_1;Z)-\epsilon_N, \end{aligned}$$

and $\epsilon_N\to 0$ as $N\to\infty$. From the standard channel coding theorem and the Fano's inequality, we have (56).

For the fourth term in (53), we have

$$\lim_{N\to\infty}\frac{1}{N}H(X_2^N|W_2)=I(X_2;Y|X_1)-R_2. \tag{57}$$

The fifth term in (53) is

$$\lim_{N\to\infty}\frac{1}{N}H(W_2)=R_2. \tag{58}$$

For the sixth term in (53), we have

$$\lim_{N\to\infty}\frac{1}{N}H(X_2^N|W_2,Z^N,X_1^N)=0. \tag{59}$$

This is because for given w_2 and x_1^N, there are $2^{N(I(X_2;Y|X_1)-\epsilon_N-R_2)}$ codewords left for x_2^N. Then note that

$$\begin{aligned} I(X_2;Y|X_1)-\epsilon_N-R_2 &\overset{(1)}{\leq} I(X_2;Y|X_1)-\epsilon_N-(I(X_2;Y|X_1)-I(X_2;Z|X_1)) \\ &= I(X_2;Z|X_1)-\epsilon_N, \end{aligned}$$

where (1) is from (50), and $\epsilon_N\to 0$ as $N\to\infty$. From the standard channel coding theorem and the Fano's inequality, we have (59).

For the seventh term in (53), we have

$$\lim_{N\to\infty}\frac{1}{N}I(X_1^N,X_2^N;Z^N)\leq I(X_1,X_2;Z), \tag{60}$$

and this is from a standard technique as in [2, p. 343].

Substituting (54), (55), (56), (57), (58), (59) and (60) into (53), we have

$$\begin{aligned} \lim_{N\to\infty}\Delta &\geq I(X_1;Y)-\gamma+I(X_2;Y|X_1)-I(X_1,X_2;Z) \\ &= I(X_1;Y)-\gamma+I(X_2;Y|X_1)-I(X_1;Z)-I(X_2;Z|X_1) \\ &\overset{(a)}{=} I(X_2;Y|X_1)-I(X_2;Z|X_1)+R_1=R_e, \end{aligned} \tag{61}$$

where (a) is from (51).

Thus, $\lim_{N\to\infty}\Delta\geq R_e$ is proved.

B. Achievability of $\mathcal{L}^{(3)}$

The existence of the encoder-decoder is under the sufficient conditions that $R_e = I(X_1, X_2; Y) - I(X_1, X_2; Z)$. Given a triple (R_1, R_2, R_e), choose a joint probability mass function $p_{X_1,X_2,Y,Z}(x_1, x_2, y, z)$ such that

$$I(X_1; Y) - I(X_1; Z) \leq R_1 \leq I(X_1; Y|X_2), I(X_2; Y|X_1) - I(X_2; Z|X_1) \leq R_2 \leq I(X_2; Y|X_1), R_1 + R_2 \leq I(X_1, X_2; Y),$$

$$R_e \leq R_1 + R_2, \quad R_e = I(X_1, X_2; Y) - I(X_1, X_2; Z).$$

The confidential message sets $\mathcal{W}_1$ and $\mathcal{W}_2$ satisfy the following conditions:

$$\lim_{N\to\infty} \frac{1}{N} \log \parallel \mathcal{W}_1 \parallel = R_1, \lim_{N\to\infty} \frac{1}{N} \log \parallel \mathcal{W}_2 \parallel = R_2. \tag{62}$$

Code-book generation: Generate $2^{N(I(X_1;Y)-\epsilon_N)}$ codewords x_1^N ($\epsilon_N \to \infty$ as $N \to \infty$), and each of them is uniformly drawn from the strong typical set $T^N_{X_1}(\eta)$. Divide the $2^{N(I(X_1;Y)-\epsilon_N)}$ codewords into 2^{NR_1} bins, and each bin corresponds to a specific value in $\mathcal{W}_1$.

Analogously, generate $2^{N(I(X_2;Y|X_1)-\epsilon_N)}$ codewords x_2^N, and each of them is uniformly drawn from the strong typical set $T^N_{X_2}(\eta)$. Divide the $2^{N(I(X_2;Y|X_1)-\epsilon_N)}$ codewords into 2^{NR_2} bins, and each bin corresponds to a specific value in $\mathcal{W}_2$.

Decoding scheme: For a given y^N, try to find a pair of sequences $(x_1^N(\hat{w}_1), x_2^N(\hat{w}_2))$ such that $(x_1^N(\hat{w}_1), x_2^N(\hat{w}_2), y^N) \in T^N_{X_1X_2Y}(\epsilon)$. If there exist sequences with the same indices $\hat{w}_1$ and $\hat{w}_2$, put out the corresponding $\hat{w}_1$ and $\hat{w}_2$, else declare a decoding error.

Proof of the achievability: By using the above definitions, it is easy to verify that $\lim_{N\to\infty} \frac{\log\|\mathcal{W}_1\|}{N} = R_1$ and $\lim_{N\to\infty} \frac{\log\|\mathcal{W}_2\|}{N} = R_2$.

Then, note that the codewords of x_1^N and x_2^N are respectively upper bounded by $2^{NI(X_1;Y|X_2)}$ and $2^{NI(X_2;Y|X_1)}$. Therefore, from the standard techniques as in [18, Ch. 14], we have $P_e \leq \epsilon$.

It remains to show that $\lim_{N\to\infty} \Delta \geq R_e$, see the following.

$$\begin{aligned}
\lim_{N\to\infty} \Delta &\triangleq \lim_{N\to\infty} \frac{1}{N} H(W_1, W_2|Z^N) \\
&= \lim_{N\to\infty} \frac{1}{N} (H(W_1|Z^N) + H(W_2|Z^N, W_1)) \\
&\geq \lim_{N\to\infty} \frac{1}{N} (H(W_1|Z^N) + H(W_2|Z^N, W_1, X_1^N)) \\
&\overset{(a)}{=} \lim_{N\to\infty} \frac{1}{N} (H(W_1|Z^N) + H(W_2|Z^N, X_1^N)) \\
&= \lim_{N\to\infty} \frac{1}{N} (H(W_1, Z^N) - H(Z^N) + H(W_2, Z^N, X_1^N) - H(Z^N, X_1^N)) \\
&= \lim_{N\to\infty} \frac{1}{N} (H(W_1, Z^N, X_1^N) - H(X_1^N|W_1, Z^N) - H(Z^N) \\
&\quad + H(W_2, Z^N, X_1^N, X_2^N) - H(X_2^N|W_2, Z^N, X_1^N) - H(Z^N, X_1^N)) \\
&\overset{(b)}{=} \lim_{N\to\infty} \frac{1}{N} (H(Z^N|X_1^N) + H(W_1) + H(X_1^N|W_1) - H(X_1^N|W_1, Z^N) - H(Z^N) \\
&\quad + H(Z^N|X_1^N, X_2^N) + H(X_1^N) + H(W_2) + H(X_2^N|W_2) - H(X_2^N|W_2, Z^N, X_1^N) - H(Z^N, X_1^N))
\end{aligned}$$

$$\begin{aligned} &= \lim_{N\to\infty}\frac{1}{N}(H(W_1)+H(X_1^N|W_1)-H(X_1^N|W_1,Z^N)+H(X_2^N|W_2)+H(W_2) \\ &\quad -H(X_2^N|W_2,Z^N,X_1^N)-I(X_1^N,X_2^N;Z^N)), \end{aligned} \tag{63}$$

where (a) is from $W_1 \to (X_1^N, Z^N) \to W_2$, and (b) is from $W_1 \to X_1^N \to Z^N$ and $W_2 \to (X_1^N, X_2^N) \to Z^N$.

The first term in (63) is

$$\lim_{N\to\infty}\frac{1}{N}H(W_1) = R_1. \tag{64}$$

The second term in (63) can be bounded as follows.

$$\lim_{N\to\infty}\frac{1}{N}H(X_1^N|W_1) = I(X_1;Y) - R_1. \tag{65}$$

For the third term in (63), we have

$$\lim_{N\to\infty}\frac{1}{N}H(X_1^N|W_1,Z^N) = 0. \tag{66}$$

This is because for a given w_1, there are $2^{N(I(X_1;Y)-\epsilon_N-R_1)}$ codewords left for x_1^N. Then note that

$$\begin{aligned} I(X_1;Y)-\epsilon_N-R_1 &\le I(X_1;Y)-\epsilon_N-(I(X_1;Y)-I(X_1;Z)) \\ &= I(X_1;Z)-\epsilon_N, \end{aligned}$$

and $\epsilon_N \to 0$ as $N \to \infty$. From the standard channel coding theorem and the Fano's inequality, we have (66).

For the fourth term in (63), we have

$$\lim_{N\to\infty}\frac{1}{N}H(X_2^N|W_2) = I(X_2;Y|X_1) - R_2. \tag{67}$$

The fifth term in (63) is

$$\lim_{N\to\infty}\frac{1}{N}H(W_2) = R_2. \tag{68}$$

For the sixth term in (63), we have

$$\lim_{N\to\infty}\frac{1}{N}H(X_2^N|W_2,Z^N,X_1^N) = 0. \tag{69}$$

This is because for given w_2 and x_1^N, there are $2^{N(I(X_2;Y|X_1)-\epsilon_N-R_2)}$ codewords left for x_2^N. Then note that

$$\begin{aligned} I(X_2;Y|X_1)-\epsilon_N-R_2 &\le I(X_2;Y|X_1)-\epsilon_N-(I(X_2;Y|X_1)-I(X_2;Z|X_1)) \\ &= I(X_2;Z|X_1)-\epsilon_N, \end{aligned}$$

and $\epsilon_N \to 0$ as $N \to \infty$. From the standard channel coding theorem and the Fano's inequality, we have (69).

For the seventh term in (63), we have

$$\lim_{N\to\infty}\frac{1}{N}I(X_1^N,X_2^N;Z^N) \le I(X_1,X_2;Z), \tag{70}$$

and this is from a standard technique as in [2, p. 343].

Substituting (64), (65), (66), (67), (68), (69) and (70) into (63), we have

$$\begin{aligned} \lim_{N\to\infty}\Delta &\ge I(X_1;Y)+I(X_2;Y|X_1)-I(X_1,X_2;Z) \\ &= I(X_1,X_2;Y)-I(X_1,X_2;Z) = R_e. \end{aligned} \tag{71}$$

Thus, $\lim_{N\to\infty}\Delta \ge R_e$ is proved.

APPENDIX J

PROOF OF THEOREM 10

In this section, we prove Theorem 10. The first three bounds in Theorem 10 are the capacity region the MAC, and the proof is omitted. It remains to prove $R_e \le R_1 + R_2$ and $R_e \le I(X_1, X_2; Y) - I(X_1, X_2; Z)$, see the followings.

(Proof of $R_e \le R_1 + R_2$) The inequality is obtained by the following equation.

$$R_e \le \lim_{N\to\infty} \frac{1}{N} H(W_1, W_2|Z^N) \le \lim_{N\to\infty} \frac{1}{N} H(W_1, W_2) = R_1 + R_2. \tag{72}$$

(Proof of $R_e \le I(X_1, X_2; Y) - I(X_1, X_2; Z)$) The proof is obtained by the following (73).

$$\begin{aligned}
R_e &\le \lim_{N\to\infty} \frac{1}{N} H(W_1, W_2|Z^N) \\
&\overset{(a)}{\le} \lim_{N\to\infty} \frac{1}{N} (H(W_1, W_2|Z^N) + \delta(P_e) - H(W_1, W_2|Z^N, Y^N)) \\
&= \lim_{N\to\infty} \frac{1}{N} (I(W_1, W_2; Y^N|Z^N) + \delta(P_e)) \\
&= \lim_{N\to\infty} \frac{1}{N} (H(Y^N|Z^N) - H(Y^N|Z^N, W_1, W_2) + \delta(P_e)) \\
&\le \lim_{N\to\infty} \frac{1}{N} (H(Y^N|Z^N) - H(Y^N|Z^N, W_1, W_2, X_1^N, X_2^N) + \delta(P_e)) \\
&\overset{(b)}{=} \lim_{N\to\infty} \frac{1}{N} (H(Y^N|Z^N) - H(Y^N|Z^N, X_1^N, X_2^N) + \delta(P_e)) \\
&= \lim_{N\to\infty} \frac{1}{N} (I(Y^N; X_1^N, X_2^N|Z^N) + \delta(P_e)) \\
&= \lim_{N\to\infty} \frac{1}{N} (I(Y^N; X_1^N, X_2^N) - I(Z^N; X_1^N, X_2^N) + \delta(P_e)) \\
&= \lim_{N\to\infty} (\frac{1}{N} \sum_{i=1}^{N} (H(Y_i|Y^{i-1}) - H(Y_i|X_{1,i}, X_{2,i}) \\
&\quad -H(Z_i|Z^{i-1}) + H(Z_i|X_{1,i}, X_{2,i})) + \frac{1}{N}\delta(P_e)) \\
&\le \lim_{N\to\infty} (\frac{1}{N} \sum_{i=1}^{N} (H(Y_i|Y^{i-1}) - H(Y_i|X_{1,i}, X_{2,i}) \\
&\quad -H(Z_i|Z^{i-1}, Y^{i-1}) + H(Z_i|X_{1,i}, X_{2,i})) + \frac{1}{N}\delta(P_e)) \\
&\overset{(c)}{=} \lim_{N\to\infty} (\frac{1}{N} \sum_{i=1}^{N} (H(Y_i|Y^{i-1}) - H(Y_i|X_{1,i}, X_{2,i}) \\
&\quad -H(Z_i|Y^{i-1}) + H(Z_i|X_{1,i}, X_{2,i})) + \frac{1}{N}\delta(P_e)) \\
&\overset{(d)}{\le} \lim_{N\to\infty} (\frac{1}{N} \sum_{i=1}^{N} (H(Y_i) - H(Y_i|X_{1,i}, X_{2,i}) \\
&\quad -H(Z_i) + H(Z_i|X_{1,i}, X_{2,i})) + \frac{1}{N}\delta(P_e)) \\
&\overset{(e)}{\le} \lim_{N\to\infty} (H(Y) - H(Y|X_1, X_2)
\end{aligned}$$

$$
\begin{aligned}
& -H(Z)+H(Z|X_1,X_2)+\frac{1}{N}\delta(P_e)) \\
= \quad & \lim_{N\to\infty}(I(X_1,X_2;Y)-I(X_1,X_2;Z)+\frac{1}{N}\delta(P_e)) \\
\overset{(f)}{\leq} \quad & \lim_{N\to\infty}(I(X_1,X_2;Y)-I(X_1,X_2;Z)+\frac{1}{N}\delta(\epsilon)) \\
= \quad & I(X_1,X_2;Y)-I(X_1,X_2;Z), \qquad (73)
\end{aligned}
$$

where (a) is from the Fano's inequality, and (b) is from $(W_1,W_2)\to(Z^N,X_2^N,X_1^N)\to Y^N$, (c) is from $Z^{i-1}\to Y^{i-1}\to Z_i$, (d) is from $Y^{i-1}\to Y_i\to Z_i$, (e) is from the definitions that $X_1\triangleq(X_{1,J},J)$, $X_2\triangleq(X_{2,J},J)$, $Y\triangleq Y_J$, $Z\triangleq Z_J$ where J is a random variable (uniformly distributed over $\{1,2,...,N\}$), and it is independent of $X_{1,i}$, $X_{2,i}$, Y_i and Z_i, and (f) is from $P_e\leq\epsilon$.

The proof of Theorem 10 is completed.

APPENDIX K

PROOF OF THEOREM 12

Theorem 12 is proved by calculating the mutual information terms in $\mathcal{C}_s^{(G)}$ and $\mathcal{C}_s^{(H)}$, see the following.

All the random variables take values in $\{0,1\}$. Let $Pr\{X_1=0\}=\alpha$, $Pr\{X_1=1\}=1-\alpha$, $Pr\{X_2=0\}=\beta$ and $Pr\{X_2=1\}=1-\beta$. Note that X_1, X_2, Y and Z satisfy

$$Y=X_1\cdot X_2,\quad Z=Y\oplus Z^*, \qquad (74)$$

where X_1 is independent of X_2, and $Pr\{Z^*=0\}=1-p$, $Pr\{Z^*=1\}=p$.

The joint probability $p_{X_1X_2Y}$ is calculated by the following (75).

$$p_{X_1,X_2,Y}(x_1,x_2,y)=p_{Y|X_1,X_2}(y|x_1,x_2)p_{X_1}(x_1)p_{X_2}(x_2). \qquad (75)$$

The joint probability $p_{X_1X_2Z}$ is calculated by the following (76).

$$p_{X_1,X_2,Z}(x_1,x_2,z)=\sum_y p_{Z|Y}(z|y)p_{Y|X_1,X_2}(y|x_1,x_2)p_{X_1}(x_1)p_{X_2}(x_2). \qquad (76)$$

Then, $\mathcal{C}_s^{(G)}$ is

$$\mathcal{C}_s^{(G)}=\left\{ (R_1,R_2): \begin{array}{c} 0\leq R_1\leq h(p) \\ 0\leq R_2\leq h(p) \\ R_1+R_2\leq h(p) \end{array} \right\}. \qquad (77)$$

Moreover, $\mathcal{C}_s^{(H)}$ is

$$\mathcal{C}_s^{(H)}=\left\{ (R_1,R_2): \begin{array}{c} 0\leq R_1\leq 1 \\ 0\leq R_2\leq 1 \\ R_1+R_2\leq h(p) \end{array} \right\}. \qquad (78)$$

It is easy to see that $\mathcal{C}_s^{(G)}$ and $\mathcal{C}_s^{(H)}$ are the same for the binary case, and therefore, the secrecy capacity region for the binary case of degraded MAC-WT with non-cooperative encoders is

$$\mathcal{R}^{(J)} = \left\{ (R_1, R_2) : \begin{array}{c} 0 \leq R_1 \leq h(p) \\ 0 \leq R_2 \leq h(p) \\ R_1 + R_2 \leq h(p) \end{array} \right\}. \tag{79}$$
